With inter-reactivity we return to concepts and processes of composition and organization. We begin with the ethical composition of media subjects, their inter-affective dynamics, but as a passage to modes of organization. This is a passage from ethics to politics. As Hardt, Terranova, Armstrong, and others remind us, the emergence of agency is a *practical* matter. The multiple must be made. Media subjectivity requires experiments, especially experiments in what Spinoza calls “the art of organizing encounters” (quoted in Hardt, 1993, p. 110). In other words, we do not begin with interactivity but with inter-reactivity, while maintaining the goal of *making* interactivity: organizing encounters that enhance capacities, knowledge, and common production, and increase constituent power.

Conclusion: Monsters of Reason

From its beginnings, the “audience” signified an *expansion of participation while still criss-crossed by exclusions and hierarchies*. Early audiences were threat and promise, imbued with a set of powers and potentials that, depending on the discourse and the moment, could be enrolled into particular programs (war, mass consumption) or

targeted for regulation (cinemagoing behavior, dissenting populations). Later audience studies, with their own problematizations, increasingly invested in the audience as a site of creativity and resistance. They have left a legacy of analytic tools to understand interregnum media subjects as mutants.

From the early problematizations of audiences onwards, a notion of rationality has been at stake. At times this was predicated on a strict separation of reason and affect (e.g., in the audience-as-mass), especially when the latter was associated with instinct, animality, sentiment, id-impulses, and lower states. But as we have seen, masses were not just negated; they were *instrumentalized*. The organization of masses meant neutralizing their disruptive crowd-like elements of self-organization while encouraging their mobilizations as publics. The affective dimensions came in the form of populist passions against corruption, sensationalism as affective media, and radical media experiments that challenged governance and civilizing mechanisms. War resistance, populist uprisings, labor organizing, muckraking: these collective powers were diminished and dissuaded.

At the same time, some affective elements were deployed by transcendent mechanisms. Mobilizations for war required emotional stirrings against enemies, “white-hot mass instincts” in favor of state policy, and a majoritarian fear of dissenting subjects. These passions, however, were aligned and disciplined in the name of a public. They were organized from above by PR agencies, propaganda services, and communications agents. Collective powers were activated *and* pacified, their constituent power transformed into constituted power, and their modes of expression prescribed around desired objectives. Early problematizations sought to create an impassioned alignment and identification, a nascent manifestation of intense inter-reactivity.

This version of rationality is based on an external mechanism that, via organization, depletes subjects by dissuading them from dissent and narrowly shaping their composition as a collective. Media subjects are disempowered by this rationality at the moment it routes them through public channels (elections, feedback on proposals, petitions for attention). This rationality required a constant attention to and modification of the media subjects: tapping the necessary constituent powers to fuel commodity consumption, productive labor, and war campaigns while policing the excesses (actual as well as virtual) of their compositions.

The reactivity at the basis of collective powers is an unavoidable condition, but the point is not to mobilize them via a “community of fear and of non-cooperative imitation” (Toscano, 2005). This mode of organization transmits and binds via fear, fascination, and sadness (in the Spinozan sense of depleting what a body can do). It mobilizes and immobilizes through controlled panics. Even when capacities are enhanced, they are done so for transcendent objectives (such as the audience-as-public designed for war, audience-as-active decoder guided toward capitalist consumption, audience-as-active receiver conducted to transfer power to the state, and generally an audience organized to support constituted power). Early modes of organization alienated media subjects (separating a body from what it can

do) as well as enervated them (while depending on them). Organization is thinned out by constituted power's prescribed pathways (alignment and identification with institutional authorities). It is also predicated on dissuasion and neutralization of extremes, dissenters, and affectors. This organization depends on disaggregating the powers of that upon which it depends. A tyrannical structure of this sort leads to "a dissolved group of separate, isolated individuals, reduced to enslavement by their own passions and, in a way, crushed by a general will that is already the final and transcendental cause of their own decisions" (Del Lucchese, 2009, p. 350). Constituted power, as a transcendent organization, emerges as an "antagonistic solution" to the compositional powers of media subjects (Armstrong, 1997, p. 45).

Audience studies, in its various guises, can be seen as participating in this despotism, in the attempt to diminish mediated powers by guiding those powers toward particular constituted ends. Some audiences (consumers, receivers, publics, some interactive fans) are constituted for transcendent aims like consumption, war, persuasion, consent. Others, like social identities, active audiences, and interactivists, recognize the immanence of media powers, or at least address the ambivalence of composition/organization (e.g., third-wave feminist media studies). Now, at the "end" of the audience (and therefore of audience studies), we can recover these virtual dimensions of media subjectivity's constituent power, which for so long have been trapped in the relatively stable object "audience." What is released from the prisonhouse of audience studies? All sorts of mutants – interactors, interpassivists, interactivists, inter-reactors. More than finding names for these figures, remediation unleashes the very dynamics of *metamorphosis* that Toni Negri (2003) calls the monstrous. Here metamorphosis is more open ended – we might find among audience powers another transmutation of passions to actions, one that corresponds to a different way of transforming constituent power to constituted power, composition to organization. Another path would not seek to eliminate passions (in fact would encourage joyful passions) but seeks, through knowledge and intuition, to transform them. The goal is a subject incapable of taking command but highly capable of producing common associations.

In the interregnum, where the not-yet cannot fully be known or named, audience studies can at least learn to live with, even encourage, the monsters it has heretofore despotically organized. The attempts by audience studies to direct these monsters toward constituted ends (war, fundamentalism, alienated consumption) will ultimately appear as its own subjectivity, whose interventions increasingly appear from the outside as "the antagonistic solution" to the emergence of media democracy and its multitudes. Future audience studies will not only find more names for the mutations in media subjectivity but will describe the ways external mediating mechanisms constantly try to harness yet suppress these mutations toward constituted ends. In other words, future audience studies will see its own work as coming from a particular type of media subjectivity, one requiring its own analysis.

NOTES

- 1 Audiening here refers to the discursive practice of making and problematizing audiences.
- 2 “Media” here is not equated with transcendence but with a series of operations (extension, acceleration, conduction, connection) immanent to the ongoing composition of a collective body.
- 3 These terms are not exhaustive of the types of associations made. Moreover, the richness of the terms necessarily needs to be pared down in this chapter, not just for the sake of space but to distill the key dynamics that animate contemporary concerns.
- 4 Two actors (one from the United States and one English) were performing in productions of *Macbeth* a few blocks from each other on the Bowery. The US actor’s working-class supporters prevented completion of the performance by the English actor (considered a colonial aristocrat). Traditionally, the next night’s performance would have been cancelled. Instead, the show went on with the English actor. Protests ensued, followed by a massive police crackdown. Militiamen fired into the crowd, with 22 killed and 100 injured.
- 5 This hyperpathy remains an issue even in the most advanced technological arrangements. Sometimes it still takes place in the streets (e.g., flashmobs, Twitter-infused protests), while at other times it involves the right to disrupt, not performances, but protocols of usage (piracy, hacking, modding).
- 6 Another path through the Marxist problematic was the political economy approach. For the most part, this framework did not make claims about media subjectivity (unless one defines the corporate media system itself as a subject). But a crucial intervention within audience studies from this perspective came with Dallas Smythe’s (2001) famous “communication blindspot” argument, which directly problematized audiences as laborers. Media subjects work for advertisers – their mental labor and attention-power are the sources of commodification for networks. This laboring media subject will become important later in the chapter.
- 7 As I have argued elsewhere (2008a), Fiske’s opening up of the constituent process within media subjectivity was constrained by analytic conditions established by Stuart Hall’s encoding/decoding model (in which activity was always situated as a moment within signification). It was also an expression of its political conjuncture, locked in a Gramscian politics, in which activity matters insofar as it is a resource for organizing popular consciousness/will.

Future Directions for Political Communication Scholarship

Considering Emotion in Mediated Public Participation

Karin Wahl-Jorgensen

ABSTRACT

In this chapter, Karin Wahl-Jorgensen argues for the importance of considering the role of emotion in political communication. Throughout the history of liberal democratic thought, she explains, emotion has been treated as the polar opposite of reason and rationality, and therefore as the enemy of good citizenship. This presumption has carried over into dominant ways of analyzing mediated public participation, as exemplified in Habermas's theory of the public sphere. There is nonetheless growing empirical evidence that emotion is central in motivating and shaping political participation. Therefore, a careful consideration of the power of emotion to mobilize citizens has much to offer the field. Wahl-Jorgensen emphasizes the need to better understand the complex consequences of affective engagements in politics. She suggests that some forms of political discourse designed to elicit emotional reaction may have integrative possibilities insofar as they can foster empathy and solidarity, while others – ones that foster hatred and intolerance – may contribute to the breakdown of debate. Either way, emotion is an indispensable and growing resource in political life that we ignore at our peril.

Why has government been instituted at all? Because the passions of men will not conform to the dictates of reason and justice without constraint.

(Alexander Hamilton, cited in Holmes, 1995, p. 1)

This chapter argues that a key direction for the future of media studies centers on more careful and sustained consideration of the affective elements of communication. In particular, it explores the consequences of the “emotional deficit in political communication” (Richards, 2004), arguing that the neglect of emotion in political communication research reflects a broader blind spot or “epistemological deficit” (Benhabib, 1992) in thinking about political philosophy and democratic practice. To address this epistemological deficit we need a differentiated analysis of political emotions and their role in mobilizing and shaping the ways in which citizens participate in politics. Such an analysis may uncover the kinds of work done by different emotions and emotional appeals in political life. Further, it may show us how existing and emerging media forms and genres encourage particular emotional regimes and discourage others, with tangible political consequences.

Dominant ways of explaining why and how people participate politically draw on premises of liberal democratic theory, which imply that, ideally, participation should be based on rational, impartial, and dispassionate citizenship, to the exclusion of emotional engagement. However, over the past few decades, scholars from a variety of fields have begun to query these assumptions, on the basis of empirical evidence that suggests an emotional engagement in politics: people participate because they *care* or feel passionately about an issue, and conversely, the choice of *inaction* also comes about as a result of affective responses (Berlant, 2007; Dahlgren, 2009; cf. Gould, 2010, p. 32). As Thompson and Hoggett (2001) put it, the “point is that wishing the emotions were not there will not make them go away; they will be present in deliberative forums whether or not they are officially excluded” (p. 353). Political participation appears to be driven in large part by impulses that run counter to ideals of liberal democracy. Instead of being driven by rationality, citizens who participate appear to be fueled by passion and emotions ranging from love to hatred, and encompassing disgust, fear, compassion, and care. Scholars who have recognized the role of emotion in politics have reflected on the rise of “passionate politics,” “the politics of affect” (e.g., Goodwin, Jasper, & Polletta, 2001), and the “emotional public sphere” (e.g., Lunt & Pantti, 2007), to mention just a few labels reflecting an increased awareness of how citizen participation is shaped by emotion.

Some have argued that the focus on the ideal of the dispassionate citizen limits our thinking about how we may organize participation and creates a yawning gap between ideal and practice. For example, empirical observations about the increasingly close relationship between politics and popular culture (e.g., van Zoonen, 2005) suggest that rather than a “dumbing down” of public debate, this realignment opens up new forums and opportunities for emotional expression in public that might engage otherwise apathetic audiences (Lunt & Stenner, 2005). To Richards (2004), politics is increasingly experienced through emotional narratives about feelings and

relationships “which are constructed around individual politicians as they are around other public figures. [. . .] These narratives are psychologically realistic, which means that they include the anxieties, doubts, conflicts, and dilemmas which are to be found in our everyday emotional lives” (p. 346). Similarly, George Marcus’s work (e.g., 2002) on the political psychology of emotion has given rise to the idea of “affective intelligence” as a counter to the dominant rational choice theories of voter behavior.

Certainly the rise of a broader confessional culture which addresses and validates emotions in public has been widely documented. In his polemic against what he sees as a contemporary obsession with airing our dirty laundry in public, Frank Furedi (2004) argues that we “live in a culture that takes emotions very seriously” (p. 1). In a complex historical account, Reddy (2001) has sought to recover the political importance of emotions, suggesting that the “concept of emotions as used in the West is closely associated with the individual’s most deeply espoused goals” (p. 114). Nevertheless, the recognition of the centrality of emotions, despite its consequences for the languages of politics, has had relatively limited impact on discussion of normative ideals of citizen participation among scholars, politicians, and media practitioners alike.

The neglect of actually occurring practices is particularly worrying in the face of a long-term decline in conventional measures of public participation, including voting in elections, newspaper readership, and membership in voluntary associations (e.g., Putnam, 2001; see also Blumler & Gurevitch, 1995). The trend toward public disengagement from conventional forms of political participation suggests that we need new theoretical and practical approaches to citizen participation that recognize the complexity of the contemporary political and media environment. At the same time, there has been an “affective turn” (Clough & Halley, 2007) in cultural studies and humanities disciplines, which has spilled over into the social sciences, so that the relationship between political participation and emotion is now theorized by political scientists, philosophers, sociologists, psychologists, and literary theorists. To social movement scholars, the question of how movements draw on affective engagements has become central (e.g., Goodwin et al., 2001; Staiger, Cvetkovich, & Reynolds, 2010). For example, Thompson and Hoggett (2001) have investigated how “the emotional life of groups” impacts local political life, informed by the recognition that an overly narrow focus on rationality in politics limits an understanding of actually existing forms of participation.

Some of this scholarship draws on the useful and fundamental distinction between affect and emotion. Massumi (2002) has argued that even though the two terms are often used interchangeably (e.g., Thrift, 2008), there are important conceptual reasons to distinguish between the two. As he sees it, affect is best understood as a bodily sensation, a reaction to stimuli characterized by intensity and energy, but without a conscious orientation and interpretation. By contrast, an emotion

is a subjective content, the sociolinguistic fixing of the quality of an experience which is from that point onward defined as personal. Emotion is qualified intensity, the

conventional, consensual point of insertion of intensity into semantically and semiotically formed progressions, into narrativizable action–reaction circuits, into function and meaning. It is intensity owned and recognized. (Massumi, 2002, p. 28)

Though Massumi describes emotional reactions as *personal* first and foremost, his distinction has also become an important resource for sociologists and political scientists interested in *collective* behavior. His distinction is premised on emotion as both interpretation and narrativization of affect, or its placement in the nexus of social relations. This offers a way out of a narrowly individualist understanding of emotion, foregrounding the “fundamental principle that an emotion cannot be seen purely as an internal, individual, and private phenomenon” (Boehner, DePaula, Dorish, & Sengers, 2007, p. 280). Understanding emotion as narrativized and collective further enables us to perceive it as a potentially politicized or politicizing interpretation of bodily affect.

Along these lines, I focus on thinking about emotion in the context of mediated public participation, as the socially constructed and hence politicized interpretation of affect. Debates over emotions and their role in mediated public participation, I argue, are anchored in political thought, which has had little to offer in the way of a differentiated understanding of the varied forms of emotional engagement and expression. I hope to provide some new avenues for investigating and taking seriously the dangers and possibilities of emotion in political communication. Specifically, I suggest that instead of automatically viewing *all* emotional reaction and expression as destructive forces in political life, we need to understand that some forms of political discourse designed to elicit emotional reaction may have integrative possibilities insofar as they can foster empathy and solidarity, while others – ones that foster hatred and intolerance – may contribute to the breakdown of debate.

Emotion and Communication Studies

What is the place of emotion in work on political communication? Even if this field has largely neglected the study of emotion, it is also true that within communication studies more broadly, scholars have long been attentive to affect in the context of audience reactions and behaviors. In particular, perhaps due to the historically close relationship between communication studies and social psychology, emotion is well established on the broader research agenda of those interested in persuasion and media effects. Indeed, the very idea that media content can “affect” us highlights the affective dimension of our attitudes, values, and behaviors. For instance, Robin Nabi (e.g. 2002, 2003) has differentiated between types of emotions, including disgust, fear, and anxiety, and their consequences for behavior and policy preferences. There is now a well-established research tradition at the intersection of cognitive psychology, political science, and communication studies that takes an interest in how emotional

responses interact with cognition in the context of political decision-making. As Westen (2007) suggests, this body of work is based on the premise that the “*political brain is an emotional brain*. It is not a dispassionate calculating machine, objectively searching for the right facts, figures, and policies to make a reasoned decision” (p. xv, emphasis in original). Voters, though often well informed and politically aware, think “with their guts” (p. xv). This, in turn, implies that political campaigning ought to be premised on the central place of emotions in electoral decision-making (p. 420).

Along these lines, the crafting and effects of emotional appeals have long been central to the preoccupations of scholars and practitioners interested in political advertising (e.g., Richards, 2004). As early as 1928, the pioneering public relations expert Edward Bernays, writing to proffer advice on what strategies politicians ought to adopt to optimally sway public opinion, examined in detail the role of emotional appeals, suggesting that candidates need to harness “as many of the basic emotions as possible” (Bernays, 2004, p. 119, cited in Grabe & Bucy, 2009, p. 91). Political consultant Tony Schwartz, who crafted the notorious “Daisy ad” for Lyndon B. Johnson’s 1968 presidential campaign against Republican contender Barry Goldwater, was explicit about the centrality of emotional appeals in political campaigning. In his book *The Responsive Chord*, published in 1974, he suggested that messages ought to be crafted not primarily with attention to the *information* contained within them, but instead with an eye to the *emotional response* they may generate in the audience, or their ability to strike a “responsive chord.” Zeynep Gürsel’s (2009) ethnographic work on photojournalism at a US news magazine relatedly demonstrates that to journalists, the anticipation of audience emotional reactions to stories is at the core of their deliberations over everything from photo selection to layout:

Central to the visual appeal is wielding emotions in order to “bring the story closer” and educate the reader. Novelty of emotion reaction becomes important to photo editors because even with a story the reader might already be assumed to know, a photo-essay is meant to supply an emotional connection that might have been absent in the reader’s previous encounters with the story. (Gürsel, 2009, pp. 40–41)

In other words, scholars have long described questions of audience emotional response as inextricably linked to audience engagement, behavior, and participation. Most recently, Betsi Grabe and Eric Bucy (2009) have contributed an innovative approach to the study of electoral campaigning in their study of the visual framing of general election news between 1992 and 2004. Among other things, their work examined emotional expressions of political candidates as evidenced in television newscasts, and demonstrated the importance of political leaders’ nonverbal communication of emotion as a resource for voters’ information gathering and decision-making.

Scholars also discuss the role of emotion in political communication in the context of its relation to rationality. For example, Ted Brader’s (2006) work has looked at the role of emotional appeals in political campaigns. Brader suggested that there is a

need for a more careful analysis of emotion in political life, on the basis that “like rationality, emotion is neither good nor bad in itself. It harbors liabilities as well as benefits [. . .] Emotion, like rationality, does not ensure desirable or good outcomes; emotion assists the democratic citizen in self-governance and can facilitate manipulation and error” (pp. 194–195). Brader concluded that the

lesson and challenge for future research is not to launch a special subfield on “emotion and politics,” but rather to incorporate emotion into existing lines of research. Emotion is well integrated into the processes of political communication and behavior; it should be integrated equally as well into our studies and understanding of the same. (p. 198; see also Marcus, 2002)

Overall, there is a well-established research agenda recognizing the power of emotional *appeals* to sway audience’s political attitudes, values, and behavior and motivations to engage politically. However, these insights have often drawn on the individual-level perspectives of psychological approaches and have paid little heed to larger (collective and political) contexts. As a result, they have rarely been accompanied with theorizing about the relationship between the celebration of the *ideal* of rationality and the *reality* of affective engagements in motivating and shaping political participation. Here, I argue that we need to both understand and question the opposition between reason and emotion that underlies so much discussion of politics. When we think about what makes good citizens, in normative and practical terms, we must acknowledge a series of empirical facts about political engagement – based on the notion that “politics requires passion, in the sense of intense involvement, even if liberal democratic theory tends to cling to visions of pure rationality” (Dahlgren, 2009, p. 8). If we fail to appreciate the “emotional life of politics” (Madianou, 2005), we also fail to account for the appeal of forms of politics that fall outside liberal conceptions. A reconsideration of the place of emotion in mediated public participation, I suggest, is vital for a variety of reasons. By bridging the gap between normative ideal and practice, we may refine our conceptual frameworks for analyzing mediated public participation. Understanding the role of emotion in politics requires us to draw on a wide variety of conceptual resources from across the humanities and social sciences disciplines.

Liberal Democratic Theory and the Distrust of Emotion

Prevailing theories of liberal democracy are premised on the normative value of “inalienable” individual rights and liberties, institutionalizing the freedom of religious and political expression, as well as guaranteeing free trade and security (cf. Holmes, 1995, p. 14). Such perspectives view the right to vote as the cornerstone of

citizens' privileges, and conversely hold that citizens have the responsibility to accumulate knowledge, consider policy options from the point of view of the shared interest, and vote in regular elections (Holden, 1988). The normative and epistemological assumptions of liberal democratic theory have long pervaded accounts and assessments of political engagement and participation, in both face-to-face and mediated environments. Built into the liberal ideal is an idealization of the rational, dispassionate, and informed citizen, coupled with a clear understanding that emotional citizens make for bad subjects. As Marcus, Neuman, and MacKuen (2000) put it:

Western tradition tends to derogate the role of affect in the public sphere. Being emotional about politics is generally associated with psychological distraction, distortion, extremity and unreasonableness. Thus, the conventional view is that our capacity for and willingness to engage in reasoned consideration is too often overwhelmed by emotion to the detriment of sound political judgment. As a result, theories of democratic practice proclaim the importance of protesting against the dangers of human passion and political faction by building up institutions, rules and procedures – all intended to protect us from our emotional selves. (p. 2)

The suspicion of emotional engagement and the celebration of rationality inherent in the liberal democratic framework are linked to the circumstances of its birth. Liberal democracy evolved in part in reaction to the long-standing dominance of the church and absolutist sovereigns (Holmes, 1995) – governance institutions premised on the service of docile subjects bereft of any power to make political decisions. The novel philosophical belief in the rationality of individuals – and hence, their ability to participate in political decision-making – emerged alongside the rise of science. From the beginning, the practice of science was premised on the notion that individuals could understand the world through the systematic application of reason. The rise of ideas of individual rationality gradually chipped away at the supremacy of sovereigns and the church, in part by legitimizing demands for liberty and equality. While the Renaissance and the Enlightenment brought notions of individual reason and the rights of subjects to the forefront of a revolution in political thought, the emergent body of democratic theory also always struggled with the relationship between rationality and passion in terms of understanding the parameters of citizen participation. Thinkers such as Hobbes, Rousseau, Locke, and Mill, in spelling out the logic of a liberal state that involved rights and participation for citizens, were informed by a concern about the ability of ordinary people to exercise reason and rationality, and about the centrality of public participation as an assurance of the legitimacy of government.¹

In this respect, there has always been a tension in democratic political thought between the need to involve citizens as rational and constructive participants in the political process and the need to control what are perceived as the irrational passions of the “common people” – as individuals and as a collective. Broadly, the management and control of emotional expression has been central to Western societies. As

Norbert Elias argued in his authoritative account, *The Civilizing Process*, Western civilization has always relied on affect control structures – systematic mechanisms which regulate individual behavior to ensure the smooth functioning of society. In particular, the control of aggression has been one of the key engines of modernity. Elias thus stipulated that when “the power of a central authority grows, if over a larger or smaller area the people are forced to live in peace with each other, the molding of affects and the standards of the drive-economy are very gradually changed” (2000, p. 169). To Elias, no “society can survive without a channeling of individual drives and affects, without a very specific control of individual behavior” (p. 443). His account demonstrates the centrality of emotion in everyday life – and the central importance of controlling its expression.

In this respect, the distinction between the rationality of the *public* and the irrationality of the *crowd* has been foundational to political sociology, which has in turn informed thinking about public participation. For example, Gustave Le Bon’s book on *The Crowd* (1960), first published in 1895, captured prevailing anxiety about the place of passion in collective behavior. In Le Bon’s analysis, the individual who becomes part of the crowd is ruled by instinctual and unconscious action. An individual in a crowd is controlled by emotions and passions, “induced to commit acts contrary to his most obvious interests” (p. 32). To Le Bon and other thinkers of his era, images of collective behavior such as those summoned up by mobs, crowds, and masses warned of the emotional manipulability of the “common people” as an Achilles heel of democracy. Similarly, Robert Park, one of the leading figures of the Chicago School of Sociology, took an interest in the relationship between social organization and public participation, viewed through the lens of urban sociology. In his doctoral dissertation, *The Crowd and the Public* (1972), written at the turn of the twentieth century, Park distinguished between the crowd and the public as forms of collectivities. To Park, the public is driven by rationality and reason, the crowd by emotion and impulse (p. 80). He thus argued that only “in the crowd does anarchy in its purest form exist. As members of a public, people are at least controlled by the norms of logic” (p. 81).

The philosopher Karl Popper (1945), in his defense of the principles of liberal democracy, *Open Society*, written during World War II, explicitly set out the distinction between emotion and reason. To Popper, if

a dispute arises, then this means that those more constructive emotions and passions which might in principle help to get over it, reverence, love, devotion to a common cause, etc., have shown themselves to be incapable of solving the problem [. . .] There are only two solutions: one is the use of emotion, and ultimately of violence, and the other is the use of reason, of impartiality, of reasonable compromise. (Popper, 1945; cited in Marcus, 2002, p. 6)

Popper’s polarization of reason and emotion ultimately leads to the conclusion that “constructive emotions” are of little utility in political life, and that emotion therefore

almost inevitably becomes destructive as it is transformed into violence (cf. Marcus, 2002, p. 6). These ontological premises reveal deep-seated anxieties fundamental to dominant political theory, and explain the normative elevation of rationality and the suppression of emotion. In some respects, liberal political thought is suffused with concern about emotions (Illouz, 2007) and recognizes them as inevitable evils of political and social life. The hands-down identification of emotion as a source of violence and irrationality has meant that it has been constructed as the polar opposite of rationality. Emotional subjects, in this prevailing view, are “bad” subjects insofar as emotion precludes the rationality required for political decision-making.

Through this logic, liberal theory has dug a hole for itself that is very difficult to get out of. If emotions are inevitable but preclude the rational citizenship required by its ideal, how can citizenship be possible? The answer is one that leaves only a qualified and tenuous hope for citizenship: implicit in much of the political thought discussed here is the view that emotions are like forces of nature; they may quickly spiral out of control and therefore, if at all possible, require control, management, and suppression, regardless of their specific nature and direction. While there are good reasons for the elevation of such “affect control” (Elias, 2000), this view leaves no room for the recognition of the positive role of emotion in politics. It is a position that, in turn, has informed scholarly engagement with questions of emotion among scholars interested in mediated public participation as a pillar of democratic societies.

Problematising Liberal Democracy and the Public Sphere

Meaningful participation of citizens in mediated public debate is seen as central to the successful functioning of democracy. It is through such discussion that publics deliberate on issues that affect them, whether these issues have to do with the broad direction of policy on topics such as welfare and education, the behavior of politicians, or specific matters ranging from local planning permissions and potholes to the military involvement in Iraq, Afghanistan, and beyond. As a cornerstone of liberal democratic theory, governments require the consent of the governed for their legitimacy, and by participating in mediated public discussion, members of the public express consent or its converse (cf. Salmon & Glasser, 1995). In today’s mass societies, where political participation is largely channeled through media of mass communication (McNair, 2007), the provision of forums and sites for public participation is central to democracy.

Much of the work that seeks to assess the democratic potential of mediated public participation takes as its vantage point Habermas’s notion of the public sphere. The public sphere concept shares key ontological and normative premises with liberal democracy, even if it also departs from it in its more substantive understanding of citizen participation in politics (e.g., Awad, 2010). In *The Structural Transformation of*

the Public Sphere (1989), Habermas offered a historical study of the emergence, flourishing, and decline of the bourgeois public sphere in France, Germany, and Britain during the sixteenth, seventeenth, and eighteenth centuries, alongside the rise of trade capitalism. Members of the bourgeois class organized themselves through discussion in public settings such as coffeehouses and pubs in Britain, literary salons in France, and regular discussion groups or “table societies” in Germany. The bourgeois public sphere relied on print publications, such as pamphlets and newsletters, to facilitate a shared discussion among groups of people in different locales. Citizens organized themselves through the institutions of the public sphere to hold the state accountable for its actions. As such, the public sphere facilitated communication between citizens and the state. The discussion of the public sphere was about matters of common concern, and individual participation was premised on the ability to put aside self-interest and act impartially. In writing about the bourgeois public sphere as an historical, empirical case study, Habermas also articulated a normative ideal for how citizens ought to participate in public life; a vision of how democracies ought to function. Central to this normative ideal is the belief that citizens ought to be actively engaged in holding government accountable through public discussion. The discussion should be rational, open to all those with an interest in the issue, and participants in the discussion should be judged on the merits of their arguments, rather than on their social status. Through this procedure, the process of deliberation would enable participants to consider the situation of the generalized other in a rational fashion, barring issues of personal interest, which are not relevant to the common good. In his articulation of the public sphere ideal, Habermas ultimately implied that emotional expression, appeals, and argument should be barred from the deliberative process to ensure its rationality.

Habermas’s tale of the public sphere has been crucial in theorizing public participation through the news media. Though most scholars acknowledge that the public sphere concept is problematic, it also stepped in to fill a dire conceptual void. The notion of the public sphere has been used both in general ways, to refer to the space in which media operate to connect citizens, and in more specific ways, to examine structures of access and the institutional arrangements of mass media.

Habermas has been particularly influential among political communication scholars because his account demonstrates the centrality of news media to democratic societies (see Dahlgren, 1995, pp. 7–8). Today, the notion of the public sphere is a widely used shorthand for the institutions, including media, through which citizens deliberate about the common good to hold government accountable, or the “realm of social life where the exchange of information and views on questions of common concern can take place so that public opinion can be formed” (Dahlgren, 1995, p. 7). While the limitations of the concept are readily recognized and widely debated, it has been used by media and communication scholars as a yardstick against which to assess existing practices of public debate. Ever since the English translation of *Structural Transformation* in 1989, Anglophone scholars have drawn on the notion of the public sphere to critique mass media arrangements and sites for public partici-

pation. Sites of mediated participation analyzed in this way include conventional “old media” forms such as letters to the editor (Wahl-Jorgensen, 2007), audience participation programs (e.g., Livingstone & Lunt, 1994; McNair, Hibberd, & Schlesinger, 2003), the nature of participation in online discussion forums (e.g., Dahlberg, 2001; Friedland, 1996; Papacharissi, 2010) and, more recently, YouTube, Facebook, and Twitter (Castells, 2008), and user-generated content (Wahl-Jorgensen, Williams, & Wardle, 2010). Some of these sites are the product of media organizations’ deliberate and top-down efforts to give their audiences a voice, and are intrinsically tied to the self-understanding of journalism as a profession in the service of the public (see, for example, McNair, 2007, pp. 18–20; Street, 2001, p. 253), while others are emerging grassroots media that have been heralded as emancipatory and democratizing (e.g., Bowman & Willis, 2003). Research on mediated public participation across these forums has largely drawn on the premises of Habermas’s model, even if some of it has problematized the inherent emphasis on rationality.

The proliferation of new interactive forums has, if anything, intensified investigation of the nature of mediated public debate. These new forums present an unprecedented set of opportunities for participation, but they also come with their own distinctive limitations. Although much early scholarship in this area represented a “cyberoptimist” perspective, celebrating the perceived democratizing opportunities inherent in new technologies, more recent work has raised serious questions about the consequences of fragmentation and anonymity, which, among other problems, tend to generate a public debate that is less oriented toward civility, consensus, and rationality (e.g., Papacharissi, 2010; Witschge, 2004). The emergence of new participatory sites and forms has caused researchers to increasingly question the liberal framework of rationality and turn to alternatives, including radical democratic perspectives (e.g., Dahlberg & Siaper, 2007; Mouffe, 2005). This newer research seeks to recover the emancipatory potential of public discussion while recognizing the inherently affective, conflicted, and messy nature of debates over the grand questions that concern us all. Recognition of the complexity of contemporary public debate, in turn, has led scholars to raise questions about the feasibility and desirability of an orientation toward consensus and rationality so central to Habermas’s model.

In grappling with these questions, scholars with varied interests from within the discipline have sought to further develop and refine Habermas’s concept, which in its generality and its articulation within a specific (and distant) historical context necessarily lacks sensitivity to the nuances and varieties of contemporary forums for mediated participation. Much of this work has built on Fraser’s (1992) influential critique of Habermas’s account. Fraser challenges the notion of a singular, elite public sphere, and suggests instead that we need conceptualizations that recognize the existence – and the normative desirability – of multiple, overlapping public spheres that are sometimes competing, rather than engaging in rational-critical discussion oriented toward a consensus (e.g., Gitlin, 1998; Hauser, 1999; Squires, 2002). In arriving at this conclusion – albeit from a variety of empirical foci and theoretical perspectives – critics of Habermas have acknowledged that competing goals and

visions of the common good mean that the ideal of rational discussion may be neither attainable nor desirable in practice.

For example, DeLuca and Peebles's (2002) influential work on the Seattle anti-globalization protests sought to challenge the presumptions of rationality inherent in Habermas's model on the basis of contemporary complex media environments. As DeLuca and Peebles (2002) pointed out, Habermas's emphasis on rational-critical debate in face-to-face and written media may have been descriptive of the communication prevailing in a limited historical context. In its "privileging of rationality, embodied conversations, consensus and civility," they argue, the public sphere concept fails to capture the forms of participation made possible by today's media environment: a "televisual world characterized by image and spectacle" (DeLuca & Peebles, 2002, pp. 125, 129). Networked, electronic media, including television and the Internet, "have fundamentally transformed the media matrix that constitutes our social milieu, producing new forms of social organization and new modes of perception" (p. 131). Instead of the notion of the public sphere, they argued, we need the concept of a "public screen" as a necessary supplement. As a metaphor, the "public screen" "recognizes that most, and the most important, public discussions take place via 'screens' – television, computer, and the front page of newspapers" (p. 125). In their analysis of the spectacle produced by the World Trade Organization (WTO) protesters, they suggest that the public screen offers new political opportunities and forms for both hegemonic and dissenting voices. As such, the concept recognizes that the prevailing forms of communication today are visual and spectacular, rather than verbal and rational:

The anarchists' image event of shattering windows obeys the rules of the public screen. It both participates in and punctures the habit of distraction characteristic of the contemporary mode of perception. It participates in order to be aired – it is brief, visual, dramatic, and emotional. [. . .] In comparison to the rationality, embodied conversations, consensus, and civility of the public sphere, the public screen highlights dissemination, images, hypermediacy, spectacular publicity, cacophony, distraction, and dissent. (DeLuca & Peebles, 2002, p. 145)

DeLuca and Peebles's concept of "public screen" picks up on observations about how the mediatized environment in which contemporary political discourse takes place privileges the emotional (and the brief, visual, and dramatic) intervention. Even if emotions have always been part and parcel of political life, today's modes of mediation underwrite their expression and foregrounding in public discourse. Though their description reiterates the juxtaposition of rationality and emotion, it also highlights the empirical and normative impossibility of sustaining the Habermasian approach and offers an alternative model, which incorporates prevailing conditions. In this sense, it takes seriously the challenges of rethinking mediated public participation and incorporating affectively grounded practices of citizenship. Their approach is typical of a growing recognition that emotion needs to be taken seriously as a vital and inevitable component of political life and, hence, mediated political participation.

The Impact of Emotions on Political Life

Among the scholarship that has taken seriously the role of emotion in political life, we can crudely distinguish between approaches that view emotion as a negative feature and those that take a more positive view of it. Simply put, when political emotions contribute to the breakdown of political discussion they can be seen as a disruptive force, whereas when they foster empathy and solidarity, they may positively contribute to engagement in public debate.

Among scholars who express worries about the emotional nature of politics, some are concerned about its impact on the “quality” of public debate, while others study how particular emotions are elicited and mobilized in ways that serve to cement existing power relations and justify forms of domination. Evidence suggests that individuals are motivated to act politically on the basis of what are often *negative* emotions, including anger, fear, hatred, and disgust toward other individuals, groups, or ideas that are discursively marked out as different or “Other.” The public expression of emotions, therefore, can be socially divisive even as it mobilizes and empowers particular groups, and hence in some cases undermines the quality of public debate. For example, Sarah Ahmed (2004) examined the use of the term “disgust” in online debates over September 11. She demonstrated that the public display of this particular term is a common way of creating distance from cultural phenomena, examining how the terms “disgust,” “disgusting,” and “disgusted” were used to express disapproval of the acts of terrorism, but also of some responses to it. She argued that the expression of disgust “generates a community of those who are bound together through the shared condemnation of a disgusting object or event” (Ahmed, 2004, p. 94). Other scholars have explored how public discourse draws heavily on registers of fear to mobilize subjects. Brian Massumi’s (1993) edited volume, *The Politics of Everyday Fear*, examines what he refers to as “ambient fear” – the low-level, constant fear that pervades capitalized social space and is particularly pervasive in media discourses. Corey Robin’s (2004) book, *Fear: The History of a Political Idea*, explores the evolution of what he refers to as “political fear” or “a people’s felt apprehension of some harm to their collective well-being – the fear of terrorism, panic over crime, anxiety about moral decay – or the intimidation wielded over men and women by governments or groups” (p. 2). Although fear may be seen to generate unity and energy, Robin (2004) suggests that it is more helpful to view it as “a symptom of pervasive conflict and political unhappiness” (p. 3). An emphasis on fear, he ultimately suggests, creates divisions among groups in diverse societies and forecloses the possibility of a political culture that emphasizes freedom and rationality. As a result, fear can never be a meaningful foundation for democratic politics.

Further, critics have highlighted how even ostensibly positive emotions, including compassion and toleration, are frequently linked to discursive regimes that reinforce the power of dominant groups. Along those lines, Wendy Brown (2006) has suggested that the idea of tolerance has been deployed as a hegemonic resource

“discursively depoliticizing the conflicts whose effects it manages by analytically occluding the histories and powers constitutive of these conflicts, and by casting ‘difference’ as ontological and as an inherent site of hostility” (p. 205). Discourses of toleration, insofar as they close down debates, could be seen as practices that cover over more eruptive and dangerous emotions that threaten to destabilize the status quo in their very intensity.

These cautionary voices recognize the mobilizing potential of political emotion, and the power of the energy unleashed by it, but nevertheless suggest that we need to carefully analyze how particular emotions operate in the political field, and ultimately conclude that emotions are frequently destructive forces.

Nonetheless, even ostensibly negative emotions can serve a mobilizing and empowering role. When emotions become collective, they become political. There is nothing straightforward about this process, insofar as “structures of feeling” only gain meaning through socially constructed discourse. Social movements scholars are now interested in how emotions both energize and shape the activities of activists. For example, as Gould (2010) has argued in her analysis of the affective engagements of the feminist and queer movements, political empowerment often takes place through the labeling of emotions – as when lesbians “feeling bad” collectively relabeled their emotion as anger. Indeed, the feminist slogan “the personal is political” speaks precisely to the significance of making public, collective, and hence political the shared but discursively privatized experiences of women, including those of childcare, domestic violence, and housework, which would otherwise be relegated to the private sphere. By naming and articulating as “anger” the negative affect of “feeling bad” about the consequences of patriarchy, it becomes a public and collective emotion that empowers the angry group to take action. As such, social movements “‘make sense’ of inchoate affective states and authorize selected feelings and actions while downplaying and even invalidating others” (Gould, 2010, p. 33). Thus ideologies and discourses both emerge and are sustained through the circulation of affect (Gould, 2010, p. 33).

The recognition of the complexity of emotional appeals and responses discussed above is mirrored among scholars who have studied how emotion structures mediated public participation. This work acknowledges that emotional engagement is central to forums for mediated public participation and inevitable both in motivating participants and in shaping their contributions. However, the central role of negative emotion as a mobilizer means that it is the most fervent and angry participants who dominate the debate. Therefore, it does seem that more often than not, where emotions are part of public deliberation, there is little chance of the kind of rational consensus that Habermas and other liberal thinkers envision, and discussion is unlikely to produce mutual understanding.

Research on conventional “old media” forums for mediated public participation, like letters to the editor, demonstrates that the citizens who bother to write or otherwise “participate” are those who feel strongly about particular issues. As discussed above, political participation is often motivated by negative emotions, including

intolerance, fear, anger, hatred, and disgust. This makes participatory forums like letters to the editor sites for the airing of views that are more extreme, strongly held, and unchangeable than those of the population as a whole, as established in studies of debates on issues as varied as religion and immigration (Kerr & Moy, 2002, p. 63; Mummery & Rodan, 2003; Mutz, 2004, p. 33). For example, Mummery and Rodan (2003) suggested that Australian letter-writing debates around refugees and asylum seekers were highly polarized and inflammatory, emphasizing and exacerbating difference and intolerance rather than seeking to overcome them. Scholars generally agree that some of the ideas expressed in letters are not actually intended to invite dialogue or debate but to perpetuate intolerant views, whether they pertain to refugees (Mummery & Rodan, 2003), ethnic minorities (Richardson, 2001; Richardson & Franklin, 2003), or cultural diversity more generally (Wahl-Jorgensen, 2004). Such contributions, given their intractable positions, may close off a debate, rather than providing the conditions that nurture it. It is exactly in debates over difference where emotions are most divisive. In clashes over issues such as race, religion, ethnicity, and sexuality, contributions that are informed by fear, anger, hatred, and intolerance do little to further mutual understanding and instead perpetuate entrenched positions (e.g., Mummery & Rodan, 2003; Wahl-Jorgensen, 2004).

The polarized and angry tone of much mediated public debate has had serious consequences for views of political participation. In the context of a political culture in many Western democracies, characterized by a generally cynical attitude toward political engagements (e.g., Eliasoph, 1998), those who venture forth to engage in political discussion are often dismissed as so extreme in their positions as to verge on the insane (Wahl-Jorgensen, 2002). This not only is true for traditional news media's participatory forums, such as letters to the editor or radio phone-ins, but also characterizes descriptions of new media genre participants. For instance, in one study a focus group member, describing contributors of user-generated content, commented: "I've got a feeling that a high proportion of them might be people in hospitals with nothing better to do than sit around, people with mental health problems" (Wahl-Jorgensen et al., 2010, p. 186). Such a position clearly undermines claims that media forums for public debate have any significant role to play in contemporary democracies, and instead constructs them as "therapeutic" sites, or "safety valves" allowing the dangerously wound-up to let off steam by expressing grievances (e.g., Davis & Rarick, 1964).

In fact, the emotional pain and uncertainty that come with attempts at communicating across barriers of difference (Peters, 1999, p. 265) keep many people from engaging in conversation with different Others in the first place (Mutz, 2006; Witschge, 2004). With a proliferation of deliberative forums that has come about as a result of Internet platforms, it seems that the consequence has been a further fragmentation of public debate, leading to a multiplicity of discussions among like-minded participants rather than ones that seek to overcome difference (Papacharissi, 2010).

On the other hand, there is a significant body of work suggesting that emotionally engaged participation may have an important role to play because it fosters the

conditions for empathy. Work on television talk shows has played a central role in opening up a discussion of the need to more broadly consider the potential benefits of emotional expression in participatory media genres. These benefits, it should be said, speak to a broader understanding of participation and empowerment than that envisioned by the liberal model, which primarily emphasizes citizens' deliberation around, and reaction to, key issues of government policy. For example, Livingstone and Lunt's (1994) *Talk on Television* looked at the opportunities for regular citizens to contribute to public debate on a variety of current affairs-based daytime television talk shows, and examined how program makers encourage and discourage particular forms of participation. Their work showed that these talk shows, in enabling studio audience members to hold politicians and experts accountable, carve out a space for "attempts to confront established power with the lived experience of ordinary people" (Livingstone & Lunt, 1994, p. 160). They proposed that the television talk shows they studied, by combining opportunities for personal storytelling and public debate, may "support an emancipatory public sphere" (Livingstone & Lunt, 1994, p. 160; see also McNair et al., 2003; Squire, 2001).

Laura Grindstaff (2002) has suggested that the power of talk shows comes from how they emotionally engage their audiences, in moments of "joy, sorrow, rage or remorse expressed in visible, bodily terms" that are the "hallmark of the genre" (p. 19, 20). For these reasons, the opportunity for individuals to speak in their own emotionally charged voices on television talk shows points us toward a recognition of the complex relationship between rationality and emotion in mediated public participation, and to the ways in which an emerging personalized form of public debate is also often and inevitably emotionalized, even as it clearly ties into explicitly political issues (see also Squire, 2001). To Squire (2001), the "public emotionality of the *Oprah Winfrey Show*, for instance, has inserted 'race,' violence against women, child abuse and, through the recent Book of the Month selections, literacy and literature, into the televisual culture of citizenship" (p. 32).

Personalized storytelling, as an expressive form, clashes with ideals of rational participation because it is embodied, partial, emotional, and based on what are essentially private experiences made public. Yet citizens and journalists alike see it both as a guarantor of authenticity and as an opening to a shared understanding of how ongoing events and controversial issues affect individuals and communities precisely because it allows participants to understand the experience of the "Other," who is seen as an authentic being because she can convincingly account for her feelings (Wahl-Jorgensen, 2001). Certainly theorists have long recognized the power of storytelling to explore matters of the common good. Ted Glasser (1991) proposed that narrative can:

cut through abstractions and other obscurities and focus on the everyday meaning of life and our dealings with it. Stories enable us to think creatively and imaginatively about our experiences and the experiences of others; they empower us to interpret and thereby comprehend the endless details of life. [. . .] [Stories have a] basic role in transforming individual and essentially private experience into a shared and therefore public reality. (pp. 235–236)

This is precisely because personalized storytelling enables empathy, or the identification with and understanding of another's situation, feelings, and motives. Empathy is fundamentally an emotional reaction, even if it enables rational consideration of the issue at hand. As Daryl Koehn (1998) has argued, the use of empathy in interactions with others can radically transform one's world view and thus one's moral standpoint:

By attempting to understand what an action, opportunity, or benefit means to this other party on her own terms, we open ourselves to substantial shifts in the way in which we have thus far thought about these matters. Empathy allows someone else's experience and perspective to become a part of our moral baseline and therefore can function to help us overcome prejudices and misconceptions. (p. 57)

The rise of the talk show and other populist genres that open up opportunities for emotional expression in public – and hence the mobilization of empathy – has occurred alongside a set of broader debates about changes in languages and registers of political discourse which see the emotionalization of public expression as a powerful emerging resource for cultivating engagement and understanding. These changes result from the increasing scrutiny of the few and the powerful by the many, or the “transformation of visibility” (Thompson, 1995). The dominance of television as the medium for communicating politics has meant that visual imagery, charisma, and personality have come to the forefront of coverage of politics, resulting in the personalization of politics (e.g., Langer, 2010). Political coverage focuses overwhelmingly on the personalities and personal lives of political leaders. Concretely, this has meant that political leaders, in their attempts to communicate with the public, are drawing on the very same strategies of personalized and emotionalized storytelling embodied in formats such as the television talk shows. For political leaders, the ability to show themselves as “human” through emotional expression is now seen as a central quality for leadership, and the personalized and emotionalized performance is part of the ritual “character test” of the election campaign, as candidates now routinely subject themselves to the scrutiny of talk shows and the narrativization of their personal lives. That a performance of emotionality is central to the ritual of political performance was powerfully demonstrated in the prominence given to glimpses of candidate emotion, for example, extensive coverage of the tears of Hillary Clinton and Joe Biden during the 2008 presidential election campaigns in the United States, and, in the UK, those of Gordon Brown on Piers Morgan's interview program in 2010.

More broadly, the process of personalization is also informed by the close relationship between popular culture and politics. As Richards (2004) suggested, that “popular culture is increasingly entering and shaping politics, *constituting* everyday politics in the content and channels of political communications, in the dynamics of public opinion, and in the values and decisions of individual citizens” (p. 342). Among other things, politicians draw on the genres, languages, and styles of popular culture, while popular culture figures are involved in politics (Louw, 2010; Street, 2001; van Zoonen,

2000, 2005). This development significantly contributes to the emotionalization of politics, insofar as “the popular has always to some extent been a domain of passion, and of emotional release” (Richards, 2004, p. 342). It signals the importance of understanding the emotive roots of our political commitments, as well as our emotional responses to policies and politicians (Richards, 2004, p. 347). This, in turn, necessitates the recognition that reasonable matters may be dramatized in an emotional fashion through the theater of public life (Richards, 2004, p. 339). The mediatization of political life, in turn, enables and underwrites such emotional dramatization. As Thrift (2008) has argued, “political presentation increasingly conforms to media norms of presentation which emphasize the performance of emotion as being an index of credibility. Increasingly, political legitimation arises from this kind of performance” (p. 184).

Overall, these developments signal the recognition of the central place of emotion in public discourse as a potential means of promoting identification and mutual understanding, and one which is not necessarily opposed to rationality. It would seem that it is, in fact, only through emotional storytelling that we can gain the empathy required for mutual understanding and, hence, for accessing horizons beyond those of our own self-interest to act as informed citizens. As such, the *positive* emotion of empathy – elicited, in turn, through emotional storytelling – is indispensable for a political discussion that moves us beyond the absolutist and entrenched parameters that often result from the play of *negative* emotions. As Mansbridge (2003) put it, if “emotional as well as rational commitments are required for people to experience the good of the whole even when their narrow self-interest conflicts with that good, then emotions must play a legitimate role in deliberation” (p. 198). Clearly, therefore, far from assuming that emotions have no place in public, or that they are naturally and invariably opposed to rationality, we need to understand the complex interplay of the range of distinctive positive and negative emotions, and how they structure public participation.

Conclusion

Taken together, the work of sociologists, philosophers, and media and communication scholars alerts us to the significance of emotion as a force in political life. Among other things, this body of work demonstrates that emotion cannot be excluded from considerations of politics, but should rather be understood as integral to its expressive forms and the ways in which citizens engage with it, and that rationality does not necessarily preclude emotion. On the contrary, emotional engagement enables the empathy necessary for citizens to fully understand the issues that concern us all. Through emotional storytelling, what are often abstract issues of the common good are given specificity that enables identification and understanding between participants and audiences.

Nonetheless, as I have discussed, emotion is not always a constructive force in politics. First of all, many of the emotions that mobilize political participation are negative, such as fear, anger, and disgust. Second, emotional involvement also has a well-documented polarizing effect on public discourse, which often renders civil deliberation impossible and instead leads to arguments based on irreconcilable differences that are unlikely to ever bring about constructive resolution, whether through consensus, negotiation, or other strategies.

To do justice to actually existing political practice, scholars must begin to engage with the concrete ways in which particular emotions encourage particular forms of public participation and expression while discouraging others, and to understand how power relations in society are productive of particular affective constellations. This effort should also entail a careful consideration of how to structure forums for public participation in ways that create conditions for public debate that work meaningfully across boundaries of difference and disagreement. In an environment of ever-proliferating sites and opportunities for public discussion, we need to raise questions about how to create forums that generate empathy instead of closing down the mutual understanding we need to make democracies work. We cannot automatically share the utopian position that more participation and discussion is better for democracy (cf. Møller Hartley, 2011), but instead must cultivate forums and procedures of mediated public participation that can foster empathy and solidarity, while recognizing the limitations of others that perpetuate division and difference.

Indeed, after an early rush to support a plethora of participatory sites enabled by online technologies, news organizations are now making difficult decisions about scaling back their involvement in forums that have offered little in the way of constructive public debate. To give just one example, after research on the BBC's practices around user-generated content demonstrated that message boards were disliked by both journalists and audience members for the incivility and negativity that they fostered (Wardle & Williams, 2008), the corporation has decided to significantly limit their use. At the same time, experiments with citizen journalism continue to foster optimism about the ability of ordinary citizens to participate in public debate by drawing on their experience and expertise (Deuze, Bruns & Neuberger, 2007).

Future research on political communication would do well to ask a series of key questions about the characteristics of existing and emerging forums for participation, which take into consideration the centrality of emotion and its varied manifestations. At the theoretical level, such research should be premised on the inherent role of emotion as a structuring dimension of citizenship, and seek to improve the prevailing approaches to mediated public participation with that insight in mind. At the empirical level, such research should take seriously the nature of emotional public discourse. It should chart how particular expressive sites (like message boards, talk radio, Twitter, and user-generated content) encourage particular forms of emotional expression, and understand how specific emotions (like anger, disgust, tolerance, and empathy, to mention a few complicated examples discussed here) can work to both help and hinder constructive public discussion, depending on the social, cultural, and

political contexts in which the debates unfold. Further, it should consider how these forms of emotional expression affect audiences – in other words, how audience members respond with engagement or disengagement, anger or happiness, and empathy or distancing, to name just a few possibilities. Future research in political communication should work to understand emotion as an indispensable and growing resource in political life.

The Future of New Media

Embodying Kurzweil's Singularity in Dollhouse, Battlestar Galactica, and Gamer David Golumbia

ABSTRACT

In this chapter, David Golumbia argues that computationalist ideology – the view that everything in reality is ultimately made up of computation – can be seen with particular clarity in what he calls “the uploading story.” According to this story, we human beings are on the verge of losing our human embodiment and our contact with everyday reality, and moving into a world where our minds merge with computers and we inhabit virtual realities much like those seen in videogames. A prominent exemplar of this story is found in the work of inventor and futurist Ray Kurzweil, who claims that we are heading toward a profound transformation he and others call “The Singularity.” Golumbia argues that the premise of Kurzweil’s “Singularity” reads very much like the fantastic versions of “uploading” that have been widespread in computational thought for decades. To expose the conceptual flaws in the uploading story and its incarnation in Kurzweil’s “Singularity,” Golumbia examines a selection of recent television series and films that use this story as their narrative foundation. *Dollhouse*, *Battlestar Galactica*, and *Gamer* constitute a kind of demonstrative interrogation of the uploading fantasy, Golumbia argues, revealing its central contradiction – namely, that it relies not on actual technological advances but on distortions beyond any recognizable limits of our conceptions of the human, the mind, and the body.

New Media After the Singularity

Computationalist ideology boasts no more technically accomplished, influential, or persuasive a public advocate than Ray Kurzweil.¹ It also has no influential advocate whose views jettison (often without considering them at all) so many of the hard-won insights of the centuries-long project of humanistic inquiry, including parts that intersect with pillars of the scientific enterprise. Kurzweil does not just paint what might reasonably be called the standard computationalist picture according to which mind itself and therefore human society operate almost exclusively via algorithms (a view explicated at length in both Kurzweil 1990 and 1999); he just as often takes the most extreme position possible, insisting that there truly can be nothing in the universe at any level other than computation.² Nearly inseparable from this perspective is the view that the “biological understanding” of human being is both misguided and “pessimistic” (see especially *The Singularity Is Near*, 2005, p. 12). To Kurzweil this old-fashioned understanding is something we will soon shed, overcoming the “inherent limits” of our human bodies, at which point “we will be able to reengineer all of the organs and systems in our biological bodies and brains to be vastly more capable” than they are today (Kurzweil, 2005, p. 27).

In Kurzweil’s future, once we understand the deep ubiquity of computation, it will become impossible to talk about something distinct called *media*: “as virtual reality from within the nervous system becomes competitive with real reality in terms of resolution and believability, our experiences will increasingly take place in virtual environments” (Kurzweil, 2005, p. 29), in a vision not far away from the one articulated by early advocates of Virtual Reality (hereafter VR).³ According to this view, in a manner more profound than anything we see today, we will live in media when we become machines. Kurzweil sometimes portrays this transformation as a discrete event and sometimes as an ongoing process of which it is but one crucial step. Following the practice of a range of technological-eschatological thinkers, Kurzweil names it “the Singularity.”⁴

In part a kind of *ne plus ultra* of media convergence, the Singularity will have changed the world so much by 2099 that:

There is no longer any clear distinction between humans and computers.

Most conscious entities do not have a permanent physical presence.

Machine-based intelligences derived from extended models of human intelligence claim to be human, although their brains are not based on carbon-based cellular processes, but rather electronic and photonic equivalents. (Kurzweil, 1999, p. 280)

One of the cardinal reasons for approaching computationalism as an ideology rather than a philosophical framework is that computationalist thought is more interested in using rhetorical constructions to keep a certain power in place than it is in fidelity to its principles or to the facts. While Kurzweil often writes in a mode that rejects

the significance of almost everything we recognize today as “human,” declaring with near-certainty and in the present tense that in 2099, “most conscious entities do not have a permanent physical presence,” he just as often retreats into truisms and tautologies that contradict these most extreme pronouncements, or that provide rhetorical catachreses just where argument is required: “future machines will be human, even if they are not biological. This will be the next step in evolution [. . .] Most of the intelligence of our civilization will ultimately be nonbiological” (Kurzweil, 2005, p. 30). Today, in our definition of these words, the phrase “non-biological human” is a contradiction – an oxymoron on the order of “round square” or “living dead” – which does nothing to dispel its power, but much to open the question of its function. It is not a logical contradiction so much as a conceptual one: there are many things that human beings are not which would be similarly (but perhaps less centrally) meaningful if appended to the word human: non-terrestrial human; non-*homo-Sapiens* human; and so on. It also shows how critical it is to examine closely the uses and functions of the term *human*. In fact, Kurzweil uses *human* much the way he uses *mind* (in the latter case conforming fully to the “Cartesian myth” thoroughly discredited in Anglo-American philosophy no later than 1949 by Ryle’s *Concept of Mind*), collapsing fully distinct meanings to blur the most critical elements of his story.

Each of Kurzweil’s books carries a version of the same future timeline, stretching out millions of years beyond us; indeed, this is the feature of his work that he has emphasized more and more (it takes up a good part of the latter third of *The Age of Spiritual Machines*, 1999, but is the overt subject of the twice-as-long *Singularity*, 2005). Wikipedia maintains a web page of about 8,000 words, apart from his main biographical entry, devoted to these predictions. It seems critical to Kurzweil not merely to prove that a merger of human and computer is logically or physically possible, but to convince us that it *must* happen *this one way* – along the way, then, to show us that mastering the future is possible, desirable, legible. Otherwise, his thesis comes down to the view that “things will change a lot in the future” – typically, the thesis Kurzweil claims his opponents reject – rather than that this particular set of future events will come about. On the contrary, what is put at stake by Kurzweil’s predictive calculus is unpredictability, openness to possibility, and the understanding that we can’t know what will come, even if we can fantasize about it.

The Future of Cartesian Dualism

Katherine Hayles (1999) famously begins *How We Became Posthuman* by retelling what she calls “a roboticist’s dream that struck [her] as a nightmare”:

Reading Hans Moravec’s *Mind Children* [. . .] I happened upon the passage where he argues it will soon be possible to download human consciousness into a computer. To

illustrate, he invents a fantasy scenario in which a robot surgeon purees the human brain in a kind of cranial liposuction, reading the information in each molecular layer as it is stripped away and transferring the information to a computer. At the end of the operation, the cranial cavity is empty, and the patient, now inhabiting the metallic body of the computer, awakens to find his consciousness exactly the same as it was before. (p. 1)

Hayles's interrogation of the "downloading" fantasy (which now seems more often referred to as an "uploading" fantasy) explored the interstices between human and machine being. In this endeavor it is complete enough, and casts enough doubt on the cybernetic paradigm itself, that it may have obscured the need for analyses of some of the fantasy's most recent manifestations.⁵ As Kurzweil's writing and recent media both show, though, there is a fuller narrative to the uploading story, one involving commitment to a particular picture of the world that is much more detailed and specific than this brief rehearsal of Moravec (1988) suggests.

The dream Hayles reads in Moravec is not entirely original to him, as Hayles is quick to point out; it has sources in at least two sets of familiar literary-philosophical tropes. The first, visible in Moravec's story to some extent, is commonly traced back at least to Descartes: the idea that despite a commitment to secular materialism – which in the wake of scientific investigation seems to entail the physical materiality of everything in the world – mind and body remain not just conceptually but ideologically distinguishable. (To some, that is, Descartes holds on to the fundamental religious idea of the soul, even as he appears to take all of empirical science and "reason" as his starting points. This association persists to the present day.)

The second source for Moravec's story, somewhat buried but still visible in it and more prominent in other versions, is the story usually referred to as the Allegory of the Cave, found in Plato's *Republic* (514a–520a; 2007, pp. 240–248): namely that our everyday reality might somehow be a projection, representation, or dream, so that the pursuit of wisdom or knowledge can also be seen as seeing through an illusory veil to a new, transcendent reality.⁶ (We should also not lose sight of the fact that this Allegory is one of the main presentations of Plato's theory of Forms, a theory that today holds little currency among philosophers precisely because of its apparent commitment to a defined and transcendent space – a Heaven-like space – where problems of word–world reference do not occur.) These two streams have merged into a single fantasy that we find repeated endlessly in contemporary media and thought: scenarios in which we are able to remove our consciousnesses from our bodies and then put them into computers, where they (we) live "inside" the computer's representations *as we see them today from the outside*: that is, scenarios in which we can upload ourselves into something like a character in *World of Warcraft* (hereafter *WoW*), complete with some sort of virtual body relative to that world.

A rough version of the elements and background assumptions typically found in the canonical version of the uploading fantasy goes something like this:

- 1 Computers will reach a point where not just unexpected, emergent, or conscious (in general) behaviors appear to develop, but where *the phenomenon we call human consciousness* spontaneously develops within the computer.
- 2 This will coincide with an algorithmic analysis of the human brain (perhaps performed by the spontaneous consciousnesses that emerged of their own accord in the first trope) that describes the entire mind as such, so that a “human mind” *per se* can be developed as an explicit software program. By “running” this program, the computer is able to emulate (or become?) a “real” human mind.
- 3 Human beings will also develop the means to transfer or copy their (individual) minds from their bodies into computers capable of running “human mind software.”
- 4 When human beings upload themselves into computers, they will be able to seamlessly slip between the “worlds” that we today perceive from outside the computer (such as games and movies) and what we call reality now. The distinction between “fiction” and “reality” will turn out to have been illusory. What today we perceive using our bodies (such as *WoW* avatars) will be “real” inside the computer.

Despite the number of features demanded by the fantasy, and despite the strange improbability of many of them happening as part of a single event or process, it is remarkable how many narratives share or respond to them, much as most vampire narratives play off or refer to, even if they do not accept, the many canonical details of the vampire story. In the uploading story, there is a strong conceptual basis for the connection between the parts, in part because they engage in the same rhetorical sleight-of-hand, subtly putting figure where ground should be, and allowing language to make logically impossible constructions appear tenable.

Accepting that there is some fantasy sense in which the uploading story could be true, programs like *Battlestar Galactica* and *Dollhouse* exploit a logical crux built into the story that is hard to see in very schematic depictions. Proposals for uploading our minds require one of two things to be possible: either (a) it is possible to *remove* our minds from our bodies, to separate out exactly that part of us that is “mind” and the part that is not, and to transfer that part exclusively to a machine, thus leaving the body an empty, un-minded husk which it seems hard to call “alive” (an aporia explored with great effectiveness in *Dollhouse*, discussed below); or (b) the human mind is or is very much like a software program, and like any software program, it can be perfectly *copied* in exactly its current state from computer to computer and medium to medium (the premise on which the *Battlestar Galactica/Caprica* franchise is built).

Read closely, the arguments Kurzweil and other uploading advocates present directly address the possibility of *copying* rather than *moving* the mind, and Kurzweil is often explicit that this is what computers will enable. But this presents a philosophical conundrum that Kurzweil’s critics seem unable to make him conceptualize.⁷ It is fundamental to our sense of human consciousness that it presents itself to itself as

unique: that is to say that the experience of embodied awareness and mental experience I am having right now is mine and mine alone, and in fact defines me, and is only accessible to me; philosophers sometimes call this “qualia.” Were it in fact possible to duplicate that entire experience somewhere else, *to make a copy of me in such a way that I were aware of it*, I would lose the core notion of uniqueness of self that is arguably constitutive of the experience of selfhood. I am not going to speculate on what my sense of self would be, were the self something that could be copied; my point is simply that the uniqueness of selfhood is a part of consciousness deeply embedded within us, and so that if the uploader’s thesis is that consciousness can be copied, he ends up reasoning in a circular fashion. Whatever “I” am, it cannot be copied; something that *can* be copied cannot be “I.” If the singularity enables the copying of consciousness, it is copying something other than what we are, either because we cannot be uploaded, or because what can upload itself *is not us*.

While the copying version of the fantasy violates its initial premise – that it is possible *exactly* to copy ourselves to a machine – the moving fantasy is far more violent, and one that even Kurzweil rarely presents in a serious fashion. One can reflect on some of the details of Moravec’s story a bit more to see this. In what state of consciousness is the patient while his brain is being pureed, even if sedated? Where is his mind if he wakes up mid-operation? Where would “he” be? When he wakes up “inside” a machine, by definition he no longer has contact with the body and bodily environment that have shaped him to that point; at the same time his body no longer has a mind. Here again, it is the apparently scientific, materialist proposal that turns out to violate mind–brain identity: my consciousness is acutely aware of things I call “my hand” and “my foot,” and while it can sustain a certain amount of challenge to these presumptions (though typically only at great pain, e.g., by amputation), it seems absurd on the face to claim that the unique version of “me” that wakes up inside the computer would “be” me, since every one of my critical representations of my body to myself would have become illusory. It is also hard to see how it could consider itself to be anything but *dead*, given that my body would be deprived of those brain functions that occur at sub- or unconscious levels while mediating autonomic body functions.⁸

In his own words, Kurzweil proposes that “there is a specific game plan for achieving human-level intelligence in a machine”:

having tracked the progress being made in accumulating all of the (yes, exponentially increasing) knowledge about the human brain and its algorithms, I believe that it is a conservative scenario to expect that within thirty years we will have detailed models of the several hundred information processing organs we collectively call the human brain. (Kurzweil, 2001)

The “several hundred information processing organs we collectively call the human brain” – while he will often enough backtrack from such sentiments, here it is clear that to Kurzweil the *brain*, *intelligence*, *mind*, and *information processing* are all the same

thing (as are “human consciousness” and “human-level intelligence”): information processing. Nevertheless, he is certain: “there will be no distinction, post-Singularity, between human and machine or between physical and virtual reality” (Kurzweil, 2005, p. 9). This is not a serious scientific or philosophical thesis but instead a powerful rhetorical construction, precisely the one we see deployed over and over again in media, regardless of its coherence.

Kurzweil’s proposals repeatedly fall victim to the kind of category error that, according to the philosopher Hilary Putnam, inform the construction of what are known in contemporary Anglo-American philosophy (in large part because of Putnam’s own work) as “brain in a vat” thought problems. Most famously, in *Reason, Truth, and History* (Putnam, 1982) Putnam asks us to consider the now-traditional scenario, in which a person’s brain

has been removed from the body and placed in a vat of nutrients which keeps the brain alive. The nerve endings have been connected to a super-scientific computer which causes the person whose brain it is to have the illusion that everything is perfectly normal. There seem to be people, objects, the sky, etc.; but really, all the person (you) is experiencing is the result of electronic impulses travelling from the computer to the nerve endings. The computer is so clever that if the person tries to raise his hand, the feedback from the computer will cause him to “see” and “feel” the hand being raised. (Putnam, 1982, p. 6)

Here Putnam reiterates the uploading story to demonstrate its incoherence. Putnam imaginatively grants what Kurzweil seems not quite to have imagined: suppose all human beings are brains in vats, we are all connected, and our hallucinatory world – our VR space – is made so as to perfectly mimic the real world that exists outside the vat. “Suppose this whole story were actually true. Could we, if we were brains in a vat in this way, *say* or *think* that we were?” Putnam asks, and then answers, “although it violates no physical law [. . .] *It cannot possibly be true*” (Putnam, 1982, p. 7, emphasis in original).

Putnam attacks the problem through logical proof, but his argument also translates, usefully for this discussion, into problems of frame and reference: although the brains in the vat “can think and ‘say’ any words we can think and say, they cannot (I claim) *refer* to what we can refer to. In particular, they cannot think or say that they are brains in a vat (*even by thinking ‘we are brains in a vat’*)” (p. 8). Another way of saying this is to reverse perspective: if we are brains in a vat, what do we mean by “reality” – the place in which the vat sits – in the first place? Is it just like the world our brains collectively imagine, or the world in which we think of ourselves as a brain in a vat? If it is what we usually think of as the “real” world in this scenario – where we can see the brain in its vat – how do we know anything about it at all? How do we know it is of such a nature to have “brains” and “vats”?⁹ This paradox applies even more strongly to versions of the story in which we see humans attached from birth to machines that generate virtual worlds, as in *The Matrix* (Wachowski &

Wachowski, 1999) – how and where, we have to ask, did those human bodies, raised from embryos by machines, gain the bodily experience with which to create the imagined environment they appear to inhabit? Part of Putnam’s point is that the only way they could have is if mind and body were two separate substances, just as there would be two different “levels” of reality to which different (but oddly duplicative) versions of ourselves have access. This view is not just bizarre; it is incoherent. Much simpler is the pragmatic and materialist picture: mind and body are one, “mind” develops as body develops, and all of its “representations,” “pictures,” and “thoughts” are constructed relative to its embodied experience.

Why, if Kurzweil’s story is correct, would our disembodied selves “inside” the computer want, as he always insists they will, to have sex, or to eat, or even to play games like *World of Warcraft*? Do we not do each of these things precisely because of the direct connections on which they rely between our “minds” and our “bodies,” unified so that we need not even think about them? Now, when humans interact with media of any sort, they do so largely because of somatic systems that may or may not rise to anything like the level of thought. Today, when my *WoW* avatar reaches a cliff edge, I experience vertigo because my somatic and perceptual systems are activating memories of and responses to such a scene, *all over my body*, not just in my brain case: it feels almost as if I am standing on the cliff edge, and if my avatar jumps, I will feel very distinctly as if I have jumped too – in my body. It is because my body is playing that game that I experience it at all. A simulated and disembodied “intelligence” version of me – the “mind” that supposedly can be extracted out of my body and uploaded to the computer world – kicks out the somatic supports that constitute the mind in the first place. The problem for Kurzweil is that his proposal is that something like *me* can be uploaded to the computer – but in every version of the scenario we are able to describe, and this is also Putnam’s insight, though we start from the premise that we can separate our minds from our bodies, the premise is legible only if we also (covertly) assume we cannot.

Kurzweil never fully posits that emergent forms of artificial intelligence (AI) will recreate human embodiment, that this embodiment might be required for human consciousness or that human brains will be raised from nascence inside a computer (indeed, to Kurzweil, “consciousness” is a relatively mystical thing that is the same regardless of where it exists; this leads to some of his wildest conclusions: after the Singularity, “our civilization will then expand outward, turning all the dumb matter and energy we encounter into sublimely intelligent – transcendent – matter and energy. So in a sense, we can say that the Singularity will ultimately infuse the universe with spirit”; Kurzweil, 2005, p. 389). He posits instead that the human brain currently *simulates* its own embodiment, as if it were dreaming all the time and as if that dream had no relation to embodied reality, and as if dreaming and reality pointed *for us* at the same thing. On this view, if we suddenly found ourselves to be brains in a vat – that is, found ourselves conscious of having been disconnected from our bodies and reduced to brains, and now were able to see that brain and that vat and its artificial hormones and its machinic embodiment – we would also inherently

know that the “brain in a vat” reality was the “real” reality. *Despite* our memory of having had a real human body, we will pass into this virtual world without recognizing that it is virtual, without consciousness that we had just given up our material existence. Again, for Kurzweil, “there will be no distinction, post-Singularity, between [. . .] physical and virtual reality” (Kurzweil, 2005, p. 9); this can only be true if the distinction between physical reality and VR has been false all along, because we are about to find out that we have always had a kind of spirit-existence, a transcendent and disembodied “intelligence” – or, in more traditional terms, a soul.

The Future of “Human Biology”

Media representations of the uploading fantasy do not just portray in exquisite detail what the fantasy entails and what it silently pushes into the background; they are themselves part of the discourse that constitutes the fantasy, so much so that the “brain in a vat” arguably occurs in science fiction narratives like *Donovan’s Brain* (novel and radio in the early 1940s, and film in 1953) before it does in philosophy or computer theory. One of the most elaborate analytical media constructions of this sort is the figure of the “humanoid Cylons” depicted in the reimagined television series *Battlestar Galactica* (Moore & Eick, 2004–2009; hereafter *BSG*) and its prequel, *Caprica* (Moore, Eick, Espenson, Murphy, & George, 2009–present). There are fantastically rich narratives in these programs that deserve sustained attention, but here I will highlight just two major representational strategies in the overall architecture of the *BSG/Caprica* world. The first is found in what is probably the central premise of the rebooted *BSG*. In the original (late 1970s) version of *Battlestar Galactica*, the robotic Cylons, while they possessed some crudely humanoid characteristics (e.g., bipedalism), were unmistakably machines. The premise of the new *BSG*, on the other hand, is that in the distant past the Cylons found a way to duplicate the biological structure of the human body and so to create infinite copies of any person’s body they choose: rather than avoiding the difficult question of whether we upload via *move* or *copy*, *BSG* embraces the copy wholeheartedly. Thus a great deal of the length of the series is devoted to the consequences of the Cylons apparently being able to create “perfect copies” of themselves, and no less to their fundamental antagonism to human life, which as in most versions of the fantasy is thematically tied to their simulative origin.

As the series progresses, the use of the copy trope itself turns out to multiply rather than reduce the *mise-en-abyme* generated by the uploading story. It turns out that each one of the “copies,” since it is indistinguishable – perhaps entirely indistinguishable – from a human being with a human consciousness, must by definition feel itself to be unique and to undergo unique experiences. Since mind and body are separate, if the body of that copy dies, its mind can then be “re-uploaded” into a new body; but this new second-generation copy has memories that no other version of

itself has. It has become unique, and rather than being copied it is actually being moved. This raises a bizarre question of origin on which the series to my knowledge never reflects. Did the Cylons learn how to “build human beings” (which we do not see), or did they learn how to separately build human *bodies* and human *brains*? Even though the latter is not the overt story, it is in fact what we see repeatedly in the series: a “dumb” body (presumably without a brain) being born in an incubator tub, into which the Number 6 consciousness, with all its particular memories intact, is downloaded. So, can the Cylons simply create as many “Number 6” models as they choose (this is demonstrated several times), and if they do so, which current Number 6 do they copy? Is there an “original” version of Number 6 that is ordinarily “used” to create a new copy? If so, why can’t the current “individual” Number 6 also be copied?

This representational abyss extends to the foundational premise of the program and eventually to its entire plot: if the Cylons are able to *perfectly* replicate human beings, what does it mean to call them “Cylons”? What does it mean to say that an entity is a perfect copy of a human being and yet is not a human being – that is, it both is X and is not X? Thus there is no attempt to distinguish at any level other than the verbal the distinction in the series between human and Cylon, but the need to use human beings in their bodies to portray the Cylons continually militates against the overt insistence that they are machines. The need for embodiment in serial television thus exposes the rhetorical trick Kurzweil tries to play with catachrestic phrases like “machines will be human”; one can say anything, but trying to realize logical and conceptual contradictions is easier said than done. The Cylons simply *are* human begins in every meaningful sense; eventually the substance of the series becomes devoted to just this conundrum, and it becomes nearly impossible for the program to offer the *characters themselves* any way to make the distinction, so that they too begin to wonder not merely whether they are human or Cylon, but also whether there is in fact any difference between the two.

The second articulation of the uploading story in these programs is found in the new *Caprica* series, a prequel series to *BSG* set in something like a near future similar to our present day, in which we see the discovery of the technology that led to the creation of the Cylons-that-are-also-humans. We learn in *Caprica* much that had not been clear in *BSG*, not least that the Cylon technology stems from the desire of its creator to reanimate the dead, and in particular a dead loved one – his daughter. (Again, where we are told we will find science, we find spiritual belief instead, and a profound enmeshment in bodily death and the persistence of the soul.) In fact, the story amplifies the aporetic qualities of its impossible central figure, Zoe: her avatar inside the VR space in *Caprica*, called “V-World,” turns out to be unique in critical ways and to violate the rules stipulated by the dramatic scenario. In the first episode of the series, “Pilot,” we meet Zoe in the flesh briefly, and we see her playing with her peers in a V-World club (called V-Club). Here avatars indulge in precisely the activities our bodies are (generally) barred from doing in physical reality: they pursue somatic pleasure in its most extreme forms, including sex, drugs, and violence.

Among the very first sequences of the series is one including not one but two virtual Zoes, both inside V-Club. Through perspective shots we are made to identify with the Zoe watching the scene from a balcony as the focal character, as the other Zoe becomes the center of attention for the sybaritic and, it appears, murderous crowd. Just as they are about to kill her, the “second” Zoe disappears, and the “real” Zoe and her friend begin to talk about the copy “eventually becoming perfect.” By the end of the Pilot the physically real (outside of V-World) Zoe dies, but the second digital copy persists inside V-World. Because she is embodied for us by the same person who plays the “real” Zoe (Alessandra Toressani), we are led to believe that this Zoe is exactly the same as the “real” Zoe, so much so that it hardly seems to feel that it is a copy, despite knowing this to be the case.

It turns out that this copy is the first instance of the “mind” or “soul” that animates the “human” Cylons, under the watchful eye of Zoe’s grieving father Daniel Graystone (played by Eric Stoltz). As the first season progresses we learn that Daniel is the founder of the company that created V-World, and that Zoe was no less gifted a programmer than he is, but was even more driven by apparently eccentric and extreme views. The viewer knows, as Daniel does not, at least at first, that Zoe was part of the radical sect that caused the explosion in which she died (possibly by design). As we learn about it in retrospect, Zoe’s work seems very familiar; it appears to have been lifted almost directly out of one of Kurzweil’s texts:

Zoe designed a program that allowed her to create a virtual duplicate of herself using a compilation of various personal records, a feat that impressed even her own computer-gifted father. Zoe believed that the creation of her holographic avatar was the next step towards a divinely-inspired plan, and designed a biofeedback subroutine that allowed her avatar to feel what she felt in the real world. (“Zoe Graystone,” 2010)

When we see Zoe inside the VR system of *Caprica*, both we and she are entirely unaware of the physically embodied Zoe; indeed, we are introduced to her specifically so as to confuse the distinction, because all sorts of bodily sensation are provided to the VR user as if this were feasible in any system like the one described in the series. Furthermore, we are told that this fantasy world, like a contemporary computer game, exists on a shared central server running computer software, so that what happens when the user plays the game sits exactly atop the blurred line between *copy* and *move*, a feint which the program plays on from the beginning. Where most users’ interaction with the game is portrayed as a “movement” of consciousness – that is, consciousness is a unique thing that can be moved out of the body, but then exists only “in” the game – Zoe is from the beginning portrayed as a “copy”; her VR “self” appears to exist whether or not the “real” Zoe is communing with the *doppelgänger*. It is hard not to see almost all of the episodes in the first season, which repeatedly dwell on images of “digital Zoe” downloading herself from V-World into a robotic Cylon frame in “real” reality, as a kind of repetition compulsion, showing the impossible entry of the “digital human self” into our reality. This is also a scene

we see repeatedly inside V-World itself: a condition is artificially imposed in which if you “die” once inside V-World, you can no longer enter it. Rather than avoiding death – pursuing immortality, following Kurzweil – all that many of the avatars appear to be able to do inside V-World is to try to end their lives, and to maintain hope that they will somehow be able to continue to live inside V-World. This special, soul-like permanence of the imagined self is granted only to Zoe, who, rather than embodying the ability to move human consciousness from site to site, instead embodies the impossible exception.

Transcending Us, or, Ending the Future

In the *BSG* enterprise and especially in *Caprica*, we see all of the elements of the uploading story realized in human bodies, including the fundamental notion that there is a world “inside” the computer that can or should be anything but a description or projection of the material world we inhabit. All such depictions rely, as do Kurzweil’s claims, on the idea of a VR system perfect enough that it fully replicates the entire human sensorium. Typically when such a scenario is fictonalized for us, only dream-like or impossible events make apparent to the viewer that this is anything but reality (contrary to “real-life” VR, where elements of physical reality have yet to be fully eliminated from the apparatus). Conceptually, it is vital to note how hard it is to depict such worlds without replicating so many features of our world that it begins to beg the question of whether a nonreal but fully immersive environment (in every sense, so that we could remotely tele-touch with another human being using the system inside the VR world) is even imaginatively coherent. Where the uploading story relies on an outmoded notion of the mind–body connection, it is no less archaic in its sturdy insistence that we will be able to live inside our dreams. Arguably, it is just the fact that they are not real in the way our experience is real that makes the transformed representations of experience in dreams, novels, movies, and videogames valuable to begin with. Mind and body, according to most current scientific and philosophical theories, are one; fiction and reality, just as undeniably, are not.

Gamer (Nevelidine & Taylor, 2009) confronts this potential aporia directly, by dispensing altogether with the idea that we might somehow synthesize experience. The movie is well known for its extended depiction of “Slayers,” a version of a videogame (almost identical to a current first-person shooter game) played in our world, but which is nevertheless controlled by players also in our world at computer terminals, (partially) immersed in the screen-world of Slayers, which thus functions as a kind of fictional experience for them. (Perhaps due to its clever focus on the fiction/reality part of the uploading fantasy, the film does create an aporia of sorts in describing an interface that both allows the in-game character [e.g., Kable, the Gerard Butler character] to retain near-complete control over his body while at the same time passing

many of these controls to the player [the 17-year-old boy Simon]. The film attributes this connection to relatively generic “self-replicating nanites” that somehow allow two consciousnesses to “exist” in a single body: the structure is aporetic in that the film does not even attempt to make clear how this kind of shared consciousness could possibly “feel” to either participant.)

Nonetheless, this conceptual crux should not distract us from the starkly credible vision of future media forms found in *Gamer*, a vision that to my knowledge is unique to the film. This becomes especially clear when we look at the second videogame presented in the movie, a version of something like *The Sims* that in the movie is called, provocatively, “Society.” In Society, we see something that looks very close to traditional VR at first: the scene opens on a sparkling, brightly colored, playful world in which the only activities appear to be based on pleasure. Using digital animation techniques, the live-action sequence of rollerbladers and skateboarders in a central city square appears clearly as part of our reality (like *Slayers*), yet also as if it is inside a videogame – which also deliberately looks like (and extends) current techniques of digital image “polishing” to originally photographed moving images. In the brief scene from Society, we watch as two very attractive skaters approach each other, as if to dance, and eventually begin kissing and touching each other. The scene pulls back and we see a vibrant city square, for some reason bounded into just that area, filled with skaters, dancers, and so on. The viewer is disoriented because she has no subjective point from which to view the scene; the characters do not jibe with any presented yet in the film, and appear to simply be enjoying some kind of drug-induced hyper-awareness. Then the scene pulls back again; the viewer sees that the Society scenes are in fact being viewed on a computer screen, but that the players of both the attractive male and female in-game characters are middle-aged, very overweight, sedentary men, greedily eating food at their computer terminals as they “play” their respective characters.

All of these scenes of Society are in fact conveyed via a talking-heads current affairs discussion program on television within the “real” reality of the film. *Slayers*, we have already learned, is positioned as a way for prisoners to shorten or even commute their sentences. Society, on the other hand, is fully or at least partly consensual: not only do the players (the obese men at their computer terminals) pay for the privilege of role-playing the characters, but all the characters inside the game (in what appears as VR world from the player’s perspective) are paid for their “work” inside the game, so that the question of its consensual nature is paralleled directly with that of sex work. In fact, we learn that the woman in the main scene we see from Society, played by the model Amber Valetta, is Kable’s wife, and eventually that both of them have been imprisoned in their game roles by a wide conspiracy headed by Castle, the man who invented both games. Then we learn that the “nanite” technology, foisted off with a few lines of jargon early in the film, entails exactly the same displacement of mind from body, the same untenable dualism, and the consequent paradoxical assertion of a mind that both does and does not inhabit the body in which it finds itself.

In *Dollhouse* (Whedon, 2009–2010), a serial television program developed for Fox by Joss Whedon and Eliza Dushku (who plays the show's focal character, Echo), we find what is arguably the fullest and most detailed portrayal of the uploading fantasy in recent media. The show, which ultimately ran for two seasons that were able to be scripted into a single story arc by Whedon et al., included some of the same conceits found in *Gamer*, articulated in much more detail than even Kurzweil has been able to do. The series reveals all of the problematic and incoherent assumptions that underlie the fantasy. In *Dollhouse*, we begin again from something like our contemporary moment and place in history, differing from ours only in the existence of some version of *copy/move* technology, allowing human consciousness as such to be copied intact from a living body to computer software and vice versa. In this version of the story, a human subject sits in a chair and has her brain "scanned" by electromagnetic probes; the result is an extracted computer program that contains the entirety of the individual's consciousness. Inversely, the "doll" sits in the chair and has someone's consciousness downloaded into her. Here, we are explicitly and necessarily told that the *copy* ability exists alongside the ability to *move*; but as I have argued, positing the availability of *copy* turns out to violate the boundaries of the self too much to sustain consistent representation. As if to emphasize the aporetic nature of this fundamental operation, the program suggests, without ever explicitly stating, that these software programs must be uniquely stored in containers that are not directly linked to a computer network. We are frequently presented with the relatively absurd spectacle of characters living sometime later than us in our world, carrying around an eight-track-tape size physical computer disk as if it were some kind of analog media and there were no way to make infinite copies of it. (Of course, it emerges at various points in the series that these files can be transmitted over computer networks and stored like any other files, putting more emphasis on the fantastic – impossible and archaic – nature of the *copy* operation itself.)

We learn about the possibility of *moving* consciousness, however, via the presentation of the show's main figure, the "doll," a human being who has voluntarily submitted to (a) having her consciousness copied into software; (b) having the consciousness in her body deleted; (c) making herself available to have other consciousnesses (and pieces of consciousnesses) downloaded into her "empty" body, which is then used to execute "client engagements" (often of a sexual nature). Sometimes the program suggests that (a) and (b) are one operation, and at other times two.

While these abilities are presented as simple and technical in the program's initial premise, this technological innovation turns out to invoke almost inevitably the entire suite of tropes in the uploading fantasy. To begin with, the idea of a "doll" – a fully functioning body that exists "without consciousness" – is impossible to comprehend and almost as hard to represent; we see at least half-a-dozen such "dolls" in their "empty" state over the course of the series, and it is never clear how the line has been drawn between the parts of the consciousness that make up the self (e.g., Echo's prior human self, Caroline) and the "consciousness of body" that allows her

instead to walk around as a “mindless” body named Echo. In fact, representation of the dolls becomes an insoluble problem for the show’s version of the uploading story, which it eventually uses as a way to resolve the series as a whole.

As an example of the dolls’ impossible status, consider that the “empty” dolls in *Dollhouse* in their uninhabited state routinely speak their normal language with complete fluency; yet when a new personality is downloaded into Echo, we see that she has learned its language(s) to perfection – while retaining Echo’s own original English fluency, regardless of whether the new character speaks English. Is language part of consciousness or isn’t it? It seems to exist in both places, but few serious accounts of consciousness would exclude all of language fluency. Are we to believe that it is doubled, existing as a whole both in the mind and in the body? And if so, what exactly are we to understand as the nature of mind and body? The dolls as well have full awareness and control of their bodies, while at the same time the downloaded consciousnesses too have control of their new “home” bodies; so who is it that experiences hunger, intimacy, sociality, interaction – the “mind” left in the doll, or the “mind” taken out of her? (That is, if Echo has control of her body, how can control of body be part of what has been transferred or copied to her “mind file”?) Third, skills and abilities work both for empty and inhabited dolls as if “written down” in abstract and disembodied form, so that for example a recorded personality will know how to do karate, and then this skill will be present in Echo on “assignment”; yet surely the knowledge of doing karate relies in large part on what have become automatic, unconscious body motions established through extensive practice and training – specific to *that* body, to that body’s nervous system, to its history, to the making-automatic of what must be thought that characterizes learning and practice. Despite Echo’s consciousness having been “removed” from her body, it seems as if a lot of it remains there – and it is no accident that this is very much how it looks in the show, as there is almost no other way to depict this, unless the body is completely deactivated, as in the brain-in-a-vat story.

All of these contradictions emerge from the simple attempt to depict a realistic scenario in which mind and body actually could be separated. Despite its seductiveness as a trope, performances of human beings in extended media like *Dollhouse* remind us to think very carefully about what we mean by the fantasies we propose and imagine. Abruptly, at the end of the first season, an epilogue (“Epitaph One”) shifts the story just 10 years into the future, showing the consequences of this technology being available – that is, of the Singularity having happened, in Kurzweil’s terms. The results are almost immediately apocalyptic. The inability for each of us to locate and understand who and what each of us are, and most especially what we are to each other, and what our bodies are, results in total social breakdown. The few remaining “Actuals” (personalities still inhabiting their original bodies) hold on to their identities with near-religious fervor, and even they do not seem entirely sure of their identities.

This projection of the future eventually twists again: toward the end of the second, final season, we revisit this 2019 scenario. This time, though, it is inside the VR world

of a body in a vat whose brain has somehow been displaced: that is, inside Echo's comatose body, pumped with fluids and wrapped into a plastic chrysalis. We learn that many such empty bodies are kept in a facility called "The Attic," and the linked bodies are stimulated with fear hormones to generate cerebral activity, effectively causing the brains to imagine their worst nightmares over and over again. That is the scenario in which the VR world becomes "real." Inside "The Attic" what appear to be the doll's original personalities exist in the apocalyptic future seen in "Epitaph One," linking together the singularity story as the series concludes. Somehow their comatose bodies and consciousnesses, living in constant fear, generate cerebral activity that can be linked, so that the series' villain, the Rossum Corporation, can build "the world's first supercomputer," allowing it to seize control of and exploit the uploading technology.

Inside *Dollhouse's* own act of telling the future, inside the VR, the technology's original developer loops through history repeatedly in his own nightmare, obsessively calculating the chances that the mind-transfer technology leads to the apocalypse, which he believes is 97% ("The Attic"). This programmed or perfectly predicted future, too, makes this character Clyde stand in very closely for something like Kurzweil's position. Now, to restore order and bring narrative closure, every other aporia must be exploited, so that Caroline/Echo is able to force herself and several other dolls back into the Attic reality and reawaken their bodies, all violating stipulations the series itself establishes. At the end of the series, after the inevitable (but likely incomplete) victory of the non-copied humans ("Actuals" in the show's terminology), we find an underlying narrative that pits interactive sociality against prediction and control as modes for imagining and controlling the future. Despite the "human" victory, the show thus ends with a number of powerful images of solipsistic self-enclosure, suggesting that the original premise of the series, because it posits mind as a kind of body-independent, mobile medium, ultimately makes impossible both human identity and human freedom.

So among the inevitable aporetic elements of the series' end is the fact that Echo, the "body without consciousness" portrayed by Eliza Dushku, turns out to have developed consciousness after all – insisting, rightly on my view, that consciousness is something like an effect of the body rather than an intact program that can be separated from it. This Echo becomes a kind of meta-consciousness, remembering and incorporating all of the selves downloaded into her body before, which *Dollhouse* can only represent as a series of discrete scenes and voices "inside" the one head of Echo. At the series' end, this singular society of minds is depicted living alone in a bunker, secreted for an unknown future, away from apocalyptic war, as if a kind of living tomb, an archive of (parts of?) the selves that are now lost. As if to emphasize the point, the series' final scenes depict Echo/Caroline uploading into herself the "self" of her boyfriend, Paul. This finale shows us a new "imagined" reality apparently inside Echo's head where the two of them meet, in an eternal space of undifferentiated closeness, but also not entirely an other, and so not providing exactly that which intimate relationships supply: the other. There are few depictions of the con-

tinued existence of the human race that so clearly also depict that future as always archived, self-enclosed, unable to refer, than the final scenes of *Dollhouse*.

The *Futur* of New Media

Throughout his writings, and especially in those of his later career, Jacques Derrida draws our attention to the linguistic and conceptual means by which we all envision, construct, plan, and inhabit the future. Most famously, Derrida persistently reflects on the distinction in French between the nouns *l'avenir* and *futur*, both of which are typically translated as the noun “the future” in English, but the first of which, a nominalized form of the standard verb “to come,” suggests for Derrida a different range of meanings from those of *le futur*:

In general, I try to distinguish between what one calls *le futur* and *l'avenir*. *Futur* is that which – tomorrow, later, next century – will be. There’s a future which is predictable, programmed, scheduled, foreseeable [Derrida pronounces each of these words in English after saying them in French]. But there is a future, *l'avenir*, to come [in English], which refers to someone who comes whose arrival is totally unexpected. For me, that is the real future. That which is totally unpredictable. The Other who comes without my being able to anticipate their arrival. So if there is a real future beyond this other known future, it’s *l'avenir* in that it’s the coming of the Other, when I am completely unable to foresee their arrival. (Derrida, quoted in Dick & Ziering, 2002)¹⁰

Despite his well-known but undeserved reputation for obliterating all differences, such passages are characteristic of Derrida, who is just as likely to discover a hidden or covert difference to which we have failed to attend as he is to suggest that a specific division (e.g., speech/writing) is in some way less than it appears. On the contrary, if there are core features of Derridean “doctrine,” one would be exactly this Levinasian insistence on the radical necessity of an openness toward the unknown, especially the unknown other.

The future we see in the singularity story stands out for its emphasis on programmability, predictability, calculation – all the qualities to which Derrida suggests we remain alert. In a wide sense, his point is that a programmed future is altogether dystopic: if we know with certainty what is going to happen there is almost no reason to deploy our wills toward those certainties; or put differently, it is hard to see what there is for our wills to do without a future open to chance and to the exercise of will.¹¹ Like the ideal world of Plato’s forms, the programmed future is a limit case that ends in perfect stasis: it is a vision that is at its core unthinkable, the full satisfaction of desire that nevertheless remains unsatisfied. The limit case of programmability is much like the limit case of immortality Hägglund (2008) sees at the heart of Derrida’s writing: what we use as a telos for so many positive practices

establishes itself as a nightmare limit. “We,” in this critical sense, cannot become immortal, because we are not immortal; when we become immortal, we lose one of the fundamental supports on which our self-definition rests. As with the rest of the uploading fantasy, whether or not there could (or do) exist immortal beings, they cannot be us.¹²

It is surely no coincidence that one site for the opposing sentiment – the view that we should and want to predict the future accurately – is found alongside the rest of the pieces of the singularity story. While futurism is found in every society, and varieties of scientific and/or scientific futurism parallel the development of science itself, there can be no denying that part of Kurzweil’s attractiveness to his constituency lies just in his repeated offering of specific, detailed accounts of future events. A standard feature of every Kurzweil text is the invocation of Moore’s Law. While today it is referred to exclusively as a “Law,” meaning something like “Physical Law,” it was originally offered by Intel co-founder Gordon Moore as a *description* of the logarithmic development of computer memory and processing power: roughly that the total power doubles every year or two (depending on which version of the Law one accepts).¹³ To Kurzweil, like other computing enthusiasts, Moore’s Law is a species of general physical laws of acceleration, which he considers vital to the coming of the Singularity:

During the 1990s, I gathered empirical data on the apparent acceleration of all information-related technologies and sought to refine the mathematical models underlying these observations. I developed a theory I call the law of accelerating returns, which explains why technology and evolutionary processes in general progress in an exponential fashion. (Kurzweil, 2005, p. 3)

Kurzweil is so sure of the inexorability of his conclusions that he confidently recounts telling James Watson (co-winner of the Nobel Prize for the discovery of DNA), in 2003, that Watson was wrong in thinking that within 50 years we will have drugs that enable us to eat all the food we want without consequence; as Kurzweil explains, in his 2005 volume, he told the “shortsighted” Watson that “these will be available in five to ten years, not fifty” (Kurzweil, 2005, p. 12).

To control, predict, and program the future: one sees this goal promoted everywhere today, so much so that despite the near-universal horror which most audiences experienced at seeing people arrested for “precrimes” in Steven Spielberg’s *Minority Report* (2002), such technologies are in fact emerging at an accelerating pace. Google and other corporations at the forefront of computational research routinely create “predictive algorithms” for a variety of domains, including human behavior.¹⁴ Such practices are a step up from, but related to, the kinds of statistical behavior prediction for which computers have long been used, primarily in military, commercial, and electoral contexts. The more one imagines oneself in the position of absolute leader, Hobbesian prince, the easier it is to see the desirability of managing the rest of the social sphere through every sort of rigid control. From such a position it follows with

a certain brutal logic that the leader is entitled to domains of knowledge-power to which those below him on the hierarchy are not entitled. In this sense there is an interesting and suggestive connection between the early parts of the uploading story and its wildest predictive aspects. Rather than pursuing real transformation of our world – a kind of transformation of “the human” that we understand well in the name of politics, especially democratic politics – Kurzweil pursues a categorical shift that relies on the stability of the very categories it claims it can transcend. It only makes sense to “transcend the human” if there will still be humans there who have not experienced the transcendence; otherwise we would all still be human. This is one of the reasons why the central focus on individual will, power, and control is so prominent and so hard to jettison in new media narratives like *Dollhouse*.

At the pinnacle of the Singularity we find paradox atop paradox. The most intense desire of the protagonists of almost every version of the story, from the Rossum Corporation to Kurzweil himself, we see again and again, is to cheat death – to become immortal. We separate the mind from the body to put it in a machine so that it can live forever. Such a desire suggests a profound failure to come to terms with one of the things that most fundamentally makes us human: death itself. Kurzweil’s frequent references to the fragility and brokenness of the human body – surely emphasizing the negative rather than positive aspects of bodily experience – famously mask a deep wound, the death of Kurzweil’s father, a loss that he seems particularly unable to accept (Vance, 2010). So does his relentless pursuit of longevity at all costs, as evidenced in his deep commitment to alternative treatments of many kinds (see, e.g., Kurzweil & Grossman, 2004). “We will gain power over our own fates,” he writes, “our mortality will be in our own hands” (Kurzweil, 2005, p. 9), both of which suggest a strikingly negative view of our present-day life. So does his philosophical position on death:

Is death desirable? The “inevitability” of death is deeply ingrained in human thinking. If death seems unavoidable, we have little choice but to rationalize it as necessary, even ennobling. The technology of the Singularity will provide practical and accessible means for humans to evolve into something greater, so we will no longer need to rationalize death as a primary means of giving meaning to life. (Kurzweil, 2005, p. 326)

It is familiar to consider Derrida’s relatively obscure writings nihilistic in some way – a quality the writings themselves do not display. However, *computationalism* (even of the high form articulated by Kurzweil), which has a much wider and more influential presence in our world than direct philosophical analysis ever could, is profoundly nihilistic with regard to our own, current, physical existence. Derrida writes often about the role of death in our sense of self: “Everyone must assume his own death, that is to say the one thing in the world that no one else can *either give or take*: therein resides freedom and responsibility” (Derrida 1995, p. 44).¹⁵ Words like “freedom” and “responsibility” occur infrequently in Kurzweil’s lexicon; he writes instead with great passion that *humans* will “transcend biology,” and presumably

transcend the freedom and responsibility that characterize our material existence. If such “deeply ingrained” parts of “human thinking” like death itself are to be jettisoned as part of that transcendence, in what sense will that new, evanescent, “sublimely intelligent” consciousness be human?

NOTES

- 1 I use “computationalism” here as I develop it in *The Cultural Logic of Computation* (2009), where I expand on the philosophical doctrine of computationalism, especially as it functioned rhetorically in Anglo-American analytic philosophy of the 1960s and 1970s, as an example of a larger conceptual, political, and rhetorical ideology committed to the view that “the mind is a computer” *whatever that might turn out to mean* – the words of the formula being more important than the particular facts. While computationalism was considered untenable for much of the 1980s and 1990s by many analytic philosophers, it is experiencing a resurgence (see Piccinini, 2010).
- 2 Something like the view that everything is computation has more serious advocates, particularly among physicists, according to which many principles of fundamental physics can be understood as encoded transmissions of information; Piccinini (2010) is the leading philosophical advocate of such views, and provides some guidance to the work in physics as well as consequences for the study of cognition, but is acutely aware of the many conceptual pitfalls Kurzweil ignores. Wolfram (2002) is the best known popularization of this work, which despite being better science than Kurzweil, seems committed to building out a very similar rhetorical-ideological structure.
- 3 This is especially clear in some of the original pronouncements of the man to whom the coinage of the term VR is usually attributed, the computer scientist and entrepreneur Jaron Lanier. Yet both technological limitations and a clear view of some of the philosophical problems described here have led him to become an especially trenchant spokesperson for what we might call the anti-Singularity perspective. Lanier (2010) provides a complete discussion of both the VR story and the current culture of computing; but see in particular Lanier (2000) for a strong technical critique of Kurzweil’s writings to that point, to which Kurzweil (2001) offers an especially contradictory and in many parts disingenuous response.
- 4 The word “singularity” occurs across discourses and with many different meanings. A detailed *New York Times* article about the “singulatarian movement” (Vance, 2010) repeatedly cites fellow travelers who do not subscribe to Kurzweil’s vision but take Kurzweil’s vision nevertheless as the central one to be contended with; the article identifies technologists no less prominent than Sergey Brin and Larry Page, co-founders of Google, as explicit followers of Kurzweil’s ideas.
- 5 An even more critical take on some of the same material in Hayles’s book is found in *The Cybernetic Hypothesis* (Tiqqun Collective, 2001), which has only recently been made widely available.
- 6 The frequent connection between mechanistic theories of mind and certain high forms of metaphysics is one of the main targets of Richard Rorty’s critical analyses: “it is pictures rather than propositions, metaphors rather than statements, which determine our philosophical convictions. The picture which holds traditional philosophy captive is that

of the mind as a great mirror, containing various representations – some accurate, some not – and capable of being studied by pure, nonempirical methods [e.g., introspection]” (Rorty, 1979, p. 12).

- 7 See, e.g., the remarkably disdainful and uncomprehending responses to his critics in Richards (2002), especially his discussion of Searle (Kurzweil, 2002), which focuses on some of the issues I raise here.
- 8 While some attention is paid to this image in *Battlestar Galactica*, the most sustained serious attempt of which I am aware to depict what it might feel like to wake up “in” a mind that has been separated from its body is Joseph McElroy’s powerful 1977 novel *Plus*, in which a dying man allows his brain to be integrated into a satellite that is then sent into Earth orbit to monitor solar events; see Proietti (2004) for a brief but well-observed and original reading of the novel that demonstrates its engagement with issues similar to those discussed here.
- 9 See “Models and Reality” (1977) for Putnam’s most detailed account of the logical problems raised by the brain-in-a-vat story.
- 10 This quote appears during roughly the first two minutes of the film. I have slightly modified the film’s English subtitles to reflect Derrida’s spoken words.
- 11 Readers of Derrida will know that the term *singularity* does occur in his writings, as has been brought out most fully by the literary critic Derek Attridge (2004). Consistent with the general difference in orientation, though, where Kurzweil uses the word to indicate a single, transcendent moment when reality shifts, in Derrida it usually occurs to gesture at the profound uniqueness of identity, to which he also attaches the term *ipseity*. Thus for Derrida we might call it part of the condition of being-in-the-world that there are singularities (and others) everywhere. The concept also occurs in Derrida’s writings on messianism and “the event,” which deserve more sustained examination than space permits.
- 12 This is a prevalent theme in fictional portrayals of immortality across space, time, and genre. Almost invariably, when a human being becomes immortal in such fictions, their primary goal instantly shifts to the pursuit not just of mortality but even of death itself, as if to realize the limit of life-without-death is to suddenly come to value death above all human things.
- 13 The original source for Moore’s Law is Gordon Moore (1965): “The complexity for minimum component costs has increased at a rate of roughly a factor of two per year. [. . .] Certainly over the short term this rate can be expected to continue, if not to increase. Over the longer term, the rate of increase is a bit more uncertain, although there is no reason to believe it will not remain nearly constant for at least 10 years” (cited in “Moore’s Law,” 2010). It was not Moore but later commentators who insisted on the lawlike nature of the description.
- 14 “Predictive analytics,” applied to any domain up to and including human behavior, is one of the fastest-growing fields of computer engineering (see “Predictive Analytics,” 2010); IBM is one of its foremost developers (as is Google). Recent work has even focused on predicting crime; marketing for such projects revels in rather than recoiling at comparisons to *Minority Report*: one press release praises “*Minority Report*-style technology being tested by two British forces following success in the United States; the system [. . .] evaluates patterns of past and present incidents, then combines the information with a range of data including crime reports, intelligence briefings, offender behavior profiles, and even weather forecasts” (“Sophisticated Crime Software,” 2010).

- 15 In addition to *The Gift of Death* (1995), for close connections between identity/ipseity, the Other, death, and futurity, see Derrida (2001, 2002) and Derrida and Roudinesco (2004).

“It’s a Nigger in Here! Kill the Nigger!”

User-Generated Media Campaigns Against Racism, Sexism, and Homophobia in Digital Games

Lisa Nakamura

ABSTRACT

Digital games scholars who study race, gender, and sexuality predominantly focus on representations – namely, the racist and sexist images and narratives found within games themselves. In this chapter, Lisa Nakamura explains that in the age of networked gaming, players often experience virulent types of discrimination not only through these representations but also at the hands of other players. In response, some players are expressing resistance to this discriminatory culture of gameplay (Nakamura, 2011a, 2011b). This chapter looks at born-digital media campaigns against racism, sexism, and homophobia such as blogs, YouTube videos, and other web-based media, examining how they document, archive, and critique instances of racism, sexism, and homophobia in live gameplay as well as within the texts of games themselves.

I’ve been a video game freak all my life. I play X-Box 360’s Need for Speed: Carbon (Electronic Arts, 2006), Gears of War (Microsoft Game Studios, 2006) and Dead or Alive 4 (Tecmo, 2006). They need Tekken (Namco) to come out on the 360. I got ideas for a racecar game and a motorcycle game. I got so many ideas, I guarantee you, people will love my ideas for games. I played Halo (Microsoft Game Studios, 2002). But when

they came up with Halo 2 (Microsoft Game Studios, 2004), it was more like for the online thing. I stopped 'cause my own team would kill me because they'd hear my voice and start calling me "nigger." "Nigger this, nigger that!" If you was right next to me at the arcade, you wouldn't say nothing. I don't ever tell them who I am, but I just forgive them for being ignorant.

(Quinton "Rampage" Jackson, quoted in Halili, 2007)

Quinton "Rampage" Jackson is a celebrity. He was the 2007 UFC Light Heavyweight mixed martial arts champion and has parlayed his skill at this popular style of no-holds-barred fighting into a career as a television and film star, appearing as Mr. T in the 2010 film based on the beloved 1970s television show *The A Team*. He is also, like many African American males in the United States, an avid videogame fan, at least until he first logged onto networked gameplay in 2004. The Xbox first offered users the ability to play online with others using the Xbox Live network in 2002. Jackson had happily played *Halo*, Bungie Studios' popular first-person shooter (FPS) science fiction game, as a non-networked game on the Xbox, but his subsequent experiences with abusive and racist language during online play drove him away.

As Jackson explained in a video interview for *Dub Magazine*, "My first time playing *Halo*, I was playing, and I said something, and someone said 'it's a nigger in here! Kill the nigger!'" The racism that Jackson experienced while playing did not originate from the programmed experience of the game but, rather, from its players. It was not the game *Halo* that offended through negative representations of African Americans or other minorities; rather, it was other players, including his "own teammates."

Jackson's experiences point to a blind spot in the field of digital games studies, a field that has been analyzed mostly as a visual medium: the discursive content of player interaction within online games is a major aspect of a game's "content." Ratings systems for games established by evaluative bodies like the ESRB (Entertainment Software Ratings Board) only take the game content itself into account when establishing its potential harm to young players. If a game lacks overt racist, sexist, or homophobic content, it may pass muster with such ratings systems. However, as Quinton Jackson discovered, networked gaming has permitted game players to play a major role in users' experience of the game.

What Jackson encountered when participating in online, multi-user games was not stereotypical players written into game scripts, but interpersonal, aural stereotyping based on the speech patterns and inflections of players. As he described in his interview, voice communication in a remote multi-player environment produces powerful new forms of voice-activated racism. These extremely popular, networked and voice-activated games permit users to broadcast their voices in gameplay, enabling a new kind of mediated race, sex, and gender discrimination. Therefore, it is crucial that media studies develop methods to study these new forms of sociality emerging on gaming platforms. The temptation to read games as the ESRB does – as static texts like film and television shows that contain quantifiable amounts of prob-

lematic “content” – ignores the reality of their usage. The things that gamers say and type to each other while playing blockbuster, triple-A games like the *Call of Duty: Modern Warfare* series are just as much a part of the game as its images, gameplay mechanics, and narrative. Indeed, the popularity of these networked games attests to users’ attraction to games as places where you can talk – and all too often, trash talk – to each other.

Digital games scholars are well aware that games change and become more challenging to study when games are played on networks rather than alone or with friends in the same room, or even in shared public spaces like arcades. We must now develop ways of taking interpersonal interaction into account when studying them. In their 2009 study of profanity in videogames, Ivory, Williams, Martin, and Consalvo cautioned that networked play added a new and understudied dimension to the study of profanity in games, and merited additional studies. Their group analyzed several popular videogames representing a variety of age-rating categories defined by the ESRB, such as “E” for Everyone, “T” for Teen, and “M” for Mature. They found that one out of five games contained one of the “seven dirty words” which are regulated in network television, as well as “words that evoke strong emotion and offense (e.g., bitch).” Although no mention is made of racist language, the study cautioned that player-produced profanity may be a greater cause for concern in the age of networked gaming than profanity scripted into games themselves. “The increasing popularity of multiplayer games and optional multiplayer game modes featuring voice interaction between players suggests that future studies should also examine the prevalence of profanity in online voice chat sessions” (Ivory et al., 2009, p. 3).

Not all profanity or abusive language experienced or found in video gameplay is the same. Player-to-player voice communications via networked FPS games like the *Halo* series, Microsoft Xbox’s original tentpole triple-A game title, are known for their profane and often abusive quality, described as “trash talk” by players and the industry alike. However, as evidenced by forum discussions on gaming websites, many gamers make a distinction between “trash talk” and discourse that crosses the line, such as use of the word “nigger.” A professional black female gamer known as “BurnYourBra,” a nationally ranked *Mortal Kombat* player, explained in an interview on a gaming website that “At tournaments players talk [crap] to each other. That’s just the way tournaments are. People get hyped. Players get salty when they lose, which is fine. But there is a difference between trash talking and calling other players disrespectful names. For me, I’ve been called a dyke, a butch, a slut, a bitch [. . .] I was even called a black bitch to my face along with being called a lesbian, a gorilla, and a monkey” (Catalyst, 2011). Unlike Jackson, who was the target of voice-activated racism in an online networked videogame, BurnYourBra was “right next to” her abuser at a games tournament.

It is easy to see why this would be more likely to happen to a female gamer than to a male player like Jackson, who is known by the stage name “Rampage” for good reason. A boxer in real life, Jackson has been described as “the baddest man on the planet”; he is a huge, imposing athlete who physically resembles the hypermuscular,

intimidating warrior avatars in fighting videogames, far more so than most of their other players and fans. As he notes in his interview, he would be unlikely to be “trash talked” in a face-to-face gaming situation like a tournament. Yet in the networked and often anonymous space of online gaming, he became the victim of racist bullying by both his own teammates and strangers.

BurnYourBra’s interview produced a lengthy comment stream on the Eventhubs.com website, many of which debated where the line between trash talking and racism should fall. Eventhubs.com, a popular gaming site “devoted to Capcom fighting games, especially the *Street Fighter* series,” states that its main purpose is to “help build a better community, encouraging players of all talent levels to share information to make the scene more competitive and widespread” (Eventhubs.com, n.d.). Some contributors to the stream agreed that “trash talk” was inevitable, indeed an intrinsic part of the competitive culture of videogame tournaments, but that it was to be distinguished from racism. Others maintained that racism is best ignored and is of little consequence in a “postracial” world, leaving it to the receiver to “shake it off.” A key paradox of race, gender, and game studies rose to the top: while profanity and abuse are “trash talk,” a form of discursive waste, lacking meaningful content that contributes to the game, many identified it as a distinctive and inevitable aspect of videogame multi-player culture, and thus to be defended. As digital media theorists Galloway and Thacker (2007) write, “trash, in the most general sense, implies remnants of something used but later discarded [. . .] trash is the set of all things that has been cast out of previous sets” (p. 145). Once trash talk has been used to intimidate or bully another player, it is supposed to disappear, absolving its user of responsibility or even memory of the event. In other words, according to a particular understanding of game etiquette, players should view trash talk as a normal part of gameplay and should not be personally offended by it.

If trash talk does not deserve notice or interpretation, as some players maintain, it is because they insist that it lacks meaning beyond the limited confines of the game. Yet, like the omnipresent trash icon on the computer desktop, a fixture of personal computer use, trash talk is part of the media ecology of digital culture. Games scholars concerned about racism and sexism have tended to pay most of their attention to racist and sexist messages within games themselves.¹ However, it is clear that in the age of networked and professional gaming, players can experience the most virulent types of discrimination and hate speech at the hands of other players, through voice-activated telepresent and co-present forms of racial and sexual harassment. Thus, just like videogame cheating, in-game economies, and online gender identities – all of which have been the subject of important book-length monographs in game studies – the discursive environment of sexism, racism, and homophobia deserves critical attention because it is central to game culture (Castronova, 2005; Consalvo, 2007; Taylor, 2006).

Moreover, if trash talk and discriminatory player interaction are part of game culture’s media ecology, so are the experiences and objections of players who do not believe that it should be dismissed as a normal, harmless aspect of gameplay. Neither

Jackson nor BurnYourBra is a well-known figure in videogame culture, and neither is known as a videogame activist. However, by sharing their experiences of racism within the culture of gaming, they are contributing toward a small but growing media campaign against videogame racism or trash talking. User-generated blogs that confront racism, sexism, and homophobia work against the impulse to forget or ignore racist trash talk by preserving and archiving it, using old and new media.

Players who have been victimized by trash talk and other forms of discriminatory player interaction are expressing a growing resistance to this culture (Nakamura, 2011a, 2011b). Born-digital media campaigns against racism, sexism, and homophobia (such as blogs, YouTube videos, and other web-based media) document, archive, and critique instances of offensive speech and behavior in live gameplay, as well as within the texts of games themselves. These media forums are fan-produced, and many identify themselves as “safe spaces” where these often unpopular critiques can be expressed. Such safe spaces are necessary, because critics of game cultures open themselves up to the ire of other fans when they call out racism, sexism, and homophobia, as the comment threads in BurnYourBra’s interview attest. Examples of these forums include Fatuglyorslutty.com, Racialicious.com, The Border House, and The Hathor Legacy, which dedicate themselves to critiquing and publicizing problems with race, gender, and sexuality in game culture, while asserting the pleasure, aesthetic value, and social importance of games.

Videogames, and the experiences of those who play them, continue to take new forms, challenging the already difficult task of studying their complex dimensions. When Quinton Jackson found himself the victim of an online lynching in *Halo* in 2004, he was part of the first wave of users playing with networked strangers, a state of affairs that has become commonplace for gamers, and one that bears close watching by media scholars, psychologists, and critical race scholars. While users have been playing with strangers on networked computers since the early days of the Internet, console gamers are newer to the world of online gaming. Since 2009 the most popular games for platforms like the Xbox 360 and the PS3 have been networked military FPS games, with *Call of Duty: Modern Warfare* and its expansions leading the way. Given the growing popularity of these types of games, it is crucial that game scholars pay close attention and develop methods of studying online interaction in console gaming.

One place to look for guidance is research on massively multi-player online role-play games, or MMORPGs. For example, Douglas Thomas (2008) and Constance Steinkuehler (2006) have written groundbreaking essays on anti-Korean and anti-Chinese racism in MMORPGs such as *Diablo 2* and *Lineage 2*. The insights and methods employed in their work would enrich studies of television-based console gamers. Both studies take player interaction and player-generated media such as quizzes and forum posts into account when analyzing these games. Thomas’s research focuses on a group of *Diablo 2* players who dubbed themselves “KPK,” or “Korean Player Killers.” Although Korea is not part of the text or narrative of *Diablo*, it becomes a meaningful and sometimes victimized racial identity in the content of

competition for game resources. Digital media studies of computer games have tended to be more adept at discussing player interaction because many of these games are networked on the Internet, and have been social for much longer. Console games are beginning to resemble these multi-user, Internet-based computer games.

Another place where game scholars can look for insights about discriminatory forms of interaction occurring in multi-user console games is in user forums emerging to address the problem. While games scholars have been slow to produce studies of this phenomenon, antiracist media campaigns by gamers are stepping into the breach. For example, The Border House blog describes itself as “Breaking Down Borders in Gaming”: “It’s a blog for those who are feminist, queer, disabled, people of color, transgender, poor, gay, lesbian, and others who belong to marginalized groups, as well as allies” (Border House, n.d.). In its policies about posting, it asks users to include “trigger warnings” about content that “involves sexual assault or violence towards women and other marginalized groups, which may distress or cause readers to be triggered” (Border House, n.d.).

Many gamers are resistant to critiquing racism, sexism, and homophobia within their favorite games. In her analysis of online player discussions about race and racism in *Grand Theft Auto*, Everett found a range of responses, “from blatant racism to racial tolerance or inclusion” (Everett & Watkins, 2008, p. 158). To combat the problem of discrimination and overcome their fear of speaking up, players have created their own Internet forums and content. Player-driven media, such as posts of abusive in-game messages and gameplay, rely upon user-generated content to produce a compelling and often hilarious evidentiary archive of egregious sexism that many female gamers experience. For example, the website *Fatuglyorslutty.com* (named after the three most common adjectives online women gamers hear during gameplay) exhorts readers to

save those awful messages you receive this weekend (and beyond) and send them in to submissions@fatuglyorslutty.com or through our submission form. You can also let us know via Twitter. And tell your friends to save their messages, too! What can you send us? We’ll accept pictures/screenshots, audio files and video recordings. Whether it’s from Xbox Live, PSN, Steam, WoW or any other game, we want to see it! (“Get ready for the weekend,” 2011)

Fatuglyorslutty’s submission page encourages users to report abuse to game moderators before posting at the site. However, it is clear the site itself addresses what the game industry cannot or will not address by publicizing sexist interactions on popular game platforms and exposing abusive gamers to public ridicule. In this, their strategy resembles Hollaback!, a “movement dedicated to ending street harassment using mobile technology” (Hollaback!, n.d.). Hollaback! encourages women to take pictures of sexual harassers and catcallers with their cellphones and to share them on their website, creating an archive for other users to access as well as a form of accountability. By collecting women and lesbian, gay, bisexual, transgender, and

queer (LGBTQ) folks' stories and pictures in a safe and shareable way with mobile phone applications, Hollaback! is creating a crowdsourced initiative to combat street harassment. Hollaback! breaks the silence that has perpetuated sexual violence internationally, asserting that any and all gender-based violence is unacceptable, and creates a space where those who have experienced verbal abuse have an option – and, more importantly, a response.

Similarly, the Fatuglyorsluty site relies exclusively on crowdsourcing to produce a rich sampling of sexist, racist slurs sent from one gamer to another in the course of gameplay on game consoles, mobile devices, within PC games like *World of Warcraft*, and on every imaginable gaming device that permits strangers to contact other strangers.

The site's successful use of humor has helped it to garner positive attention in the gaming community, quite a feat given how unpopular and divisive the topic of sexism

Figure 21.1 User-contributed screenshot from fatuglyorsluty.com. Retrieved May 1, 2011, from <http://fatuglyorsluty.com/2011/05/01/with-a-side-of-seriously-disturbing/>

has been in recent years.² A writer for Kotaku, a popular and widely read gaming blog owned by Gawker Media, wrote the following in 2011:

The casual racism, snarling sexism and random belligerence one encounters in online play, particularly in a first-person shooter over Xbox Live, is not at all a new phenomenon. It's sadly accepted as par for the course, in fact. But the three curators of "Fat, Ugly or Slutty," have chosen to archive it, not so much for a high-minded ideal, but to hold a mirror up to idiots worthy of ridicule. (Good, 2011)

Indeed, Fatuglyorsluttty.com embodies Henry Jenkins's (2006) "critically optimistic" theories about the power of participatory media. In this case, interactive media themselves offer perhaps the most effective means of combatting other, more problematic interactive media experiences.

As the Kotaku post noted, racism, sexism, and homophobia are commonplace in networked console video gameplay. Though the Xbox 360, PS2/3, and Wii all have terms of service agreements regarding the use of profanity and hate speech in live gameplay, these regulations are enforced only through a system of victim-reported

“tickets” that are acted upon well after the fact. Users who engage in hate speech can be banned from the service but are able to log back on after the ban period has passed. The ineffectiveness of industry regulation of hate speech has created a need for victims of gamer abuse to create their own participatory outlets to engage a wider public and increase awareness of this serious issue.

Players who are challenging the normalization of trash talk and discriminatory forms of multi-user gameplay are often equally insistent in their enthusiasm for games, and are careful not to attack the games themselves or videogames in their entirety. In his interview with *Dub Magazine*, for example, Jackson refrains from faulting the content of the game itself; indeed, he professes his love for the game. Instead he blames other players, rather than game developers, with creating a racially hostile, uninhabitable space for people of color.

Given the popularity of multi-user online gaming and the complex dimensions of gameplay, the future of game studies must include attention to player experiences with each other as well as with games themselves. In the remainder of this chapter, I discuss three new directions for future videogame research that I believe will help game studies to encompass a more ecological and critical perspective on player experience and interaction with games and with other gamers.

The Politics of Videogame Pleasure: Who Plays, Who Pays?

It has become unfashionable in critical circles to discuss pleasure in videogames, and more common to frame the debates in terms of “addiction.” Yet games studies scholars are missing a critical dimension by avoiding the question of pleasure in playing videogames, for this is precisely why people play them, and why they are hard to study. The notion that pleasure has a *politics* is the basis for both feminist theory and theories of race and ethnicity. The pleasurable is both personal and political, and few media are as quintessentially personal as videogames. Often enjoyed privately or in the company of anonymous or known networked co-players, they are mass-mediated, interactive products that give everyone a different kind of “happy ending.”

However, the political critique of videogame pleasure lags far behind. Such a critique requires acknowledging that much of the pleasure of videogames comes at the expense of women and people of color, both literally and figuratively, as women in Asian sweatshops manufacture the devices we use to enjoy games, as “urban” games represent Black and Latino men as thugs and criminals, and as women and people of color find themselves the victims of voice-activated discrimination in networked games. In the latter case, some argue that the problem is nil, because consoles permit users to disable voice communications. However, this constraint can harm collaborative gameplay, and is the equivalent of telling African Americans to cover their ears if words like “nigger” are shouted at them. (Moreover, suggesting that the problem

of discrimination can be solved in this way is indicative of a broader tendency to insist that there are simple technical solutions to complex social problems.) Others argue that the popularity of videogames among people of color is proof enough that discrimination is meaningless and ineffectual. To the contrary, the fact that people of color are eager consumers of videogames despite a climate of racism needs to be better understood, and certainly ought not to be invoked to validate the racial and gendered economy of game pleasure.

There is beginning to appear research and theory in games studies that more adequately addresses the complexity of these issues. Nick Dyer-Witheford and Greig de Peuter's *Games of Empire: Global Capitalism and Video Games* offers an excellent and integrated critique of race, gender, and labor within the new world gaming order (Dyer-Witheford & de Peuter, 2009). The book provides a "short history of the video game from the perspective of immaterial labor," approaching games as neoliberal texts (p. 5). Gaming's production cultures, player cultures, and textual content reflect transnational power relations, according to these authors. Each individual on the circuit of culture has a distinctive form of labor to perform, whether it is playing, modding, hardware building, or laboring within virtual world games. The Global South consumes, produces, and is represented within digital games in a very different fashion from the Global North. As this work makes clear, a challenge for future games studies is to examine the transnational context in which videogames are produced, circulated, and experienced.

Overemphasis on the Hardcore Gamer

The vast majority of videogame criticism addresses "hardcore" games despite a profound shift in recent years toward "casual," mobile, and social games.³ This is a critical gap that needs to be addressed for at least two reasons: a focus on high-learning-curve, non-interruptible, expensive "triple A" games ignores the reality of how digital games are played today and contributes toward the now-cherished identity of the gamer as a young White male who is part of geek culture. An effective and relevant games criticism will need to address non-hardcore games that constitute the majority of game hours spent.

Many videogame players and scholars tend to characterize digital games as superior to other forms of media – more interactive, more agentive, and more flexible in terms of the identities available to the user. Looking at hardcore videogames exclusively is problematic because it perpetuates the valorization of one group of users' experience over another. Women and children's engagements with games in particular will necessarily take a back seat in critical work if it continues with this narrow focus. The pleasures of casual games are underanalyzed and thus less visible, devaluing the experiences of a group of players who have often been ignored and devalued in media studies.

Ripe for research in this area are casual games developers such as Big Fish, whose products are marketed to and enjoyed primarily by middle-aged women. In fact, feminist media scholars would be wise to focus attention on casual games and their users, building on the work of scholars such as Janice Radway (1991), whose *Reading the Romance* legitimated the study of women's popular fiction texts. Radway's approach differed from that of traditional literary critics, for she studied the reader culture and forms of interaction that were enabled and invoked by the platform of romance novels. It is no accident that FPS games are prime platforms for racism, sexism, and homophobia, yet nor does the game content completely determine what occurs in players' interactions with the game and with one another. The complex and nuanced interaction between the culture produced by active audiences and the texts they interact with are important areas for future study. Feminist media scholars need to focus some attention on games if they wish to fully understand popular media use among women today.

Videogames are Both Textual and Communicative Artifacts

The news about race, gender, and sexuality in videogames can be depressing. Games depict minorities in stereotyped ways, often in fighting games, urban games, or military games.⁴ The game industry itself is extremely male-dominated and not at all racially diverse. Communication affordances between players in networked digital games are often used to transmit sexual harassment and racist hate speech (Huntemann, 2010). It is this latter type of racism that is the least studied, perhaps because it requires methods of observation, ethnography, and analysis that are unfamiliar to many humanists who are trained in textual studies. While social scientists tend to focus on game player practices and cultures, literary and software scholars such as Lev Manovich, Ian Bogost, Nick Montfort, and Noah Wardrip-Fruin treat games as relatively autonomous visual, aural, and textual artifacts. Studying game player discourse presents a different set of methodological challenges from analyzing game content alone. For games are communicative artifacts: they are autonomous texts that are also platforms of social interaction. Game texts and game interaction are co-constitutive and need to be studied together.⁵

However, it is important to conduct these studies, for if gamers are themselves the source of some of the most virulent racist, sexist, and homophobic messages in videogames, they are also the source of some of the most ingenious and potent campaigns against them. As Dyer-Witheford and de Peuter (2009) write, "games not only cultivate the imagination of alternative social possibilities; they also present practical tools that may be useful for its actualization" (p. 213). Players create viciously racist environments and discursive climates within digital games. At the same time,

other players are using the Internet to campaign against racism, sexism, and homophobia by creating their own archives of hate speech, often using humor as a weapon to mobilize support and create a community. This community ranges from the player who protests discussions of racism and sexism in games as “overreacting,” to those who mobilize the language of post-traumatic stress disorder when creating moderation policies for their fan blogs.

Conclusion

All games are social. Even single-player games have racial metacultures, or cultural artifacts and practices that are game-centered but occur outside of the context of the game, that are deeply woven into game experience (Nielsen, Smith, & Pajares Tosca, 2008). Game fans are extremely valuable resources for scholars because they are obsessive chroniclers of their own experiences, opinions, and information about games. As game scholar and evangelist Jane McGonigal notes, some of the largest and most extensive collective intelligence artifacts on the Internet are game-related: “there are [. . .] more than 65,000 WoW players who are registered contributors to WoWWiki, currently the world’s second largest wiki after Wikipedia” (McGonigal, 2011).

These are vast depositories of user-generated knowledge and new content waiting for scholars to study them. And demographic studies like the excellent series produced by the Play On group at Stanford University have contributed much to our understanding of racial and gender identity choices among *World of Warcraft* players. In a study of male players entitled “Do Men Heal More When in Drag? Conflicting Identity Cues Between User and Avatar,” Yee, Ducheneaut, Yao, and Nelson (2011) used behavioral data from more than 1,040 users in a virtual world, and discovered that men display more cooperative or supportive behavior in-game when playing as female avatars.

These studies contribute a great deal to our understanding of identity in digital games, and it is important that game scholarship continue to produce empirical studies of player behavior. But more nuanced analytical and interpretive work is needed to provide critical insights into player behavior and culture. Game fans have already produced much more detailed summaries, walkthroughs, typologies, and timelines on Wikipedia than scholars can hope to top. They are not always as ready to be critical about game cultures’ blind spots and dirty laundry. The user-generated anti-harassment media campaigns like the ones I have described here are far less well read than game blogs like Gamasutra and Kotaku. Thus, our job as scholars must extend far beyond appreciation, measurement, categorization, and justification of games as legitimate art forms and key media industries. Media scholars must address games in a critical and historical fashion, identifying how they interpellate or hail users as fans, consumers, social actors, producers, and gendered, racialized, and national subjects.

According to a 2011 report by researchers at Northwestern University, there have always been differences between White and non-White youth when it comes to frequency of media use, and these have grown significantly in recent years:

Historically, scholars have been aware of differences in the amount of time that White and minority children spend with media, especially TV. But last year's Generation M2 study indicated a large increase in the amount of time both Black and Hispanic youth are spending with media, to the point where they are consuming an average of 13 hours worth of media content a day (12:59 for Blacks and 13:00 for Hispanics), compared with about eight and a half hours (8:36) for White youth, a difference of about four and a half hours a day. In recent years, this gap in media use between White and Black youth has doubled. (Rideout, Lauricella, & Wartella, 2011)

Digital games represent a large chunk of the total time that minority youth are spending with games. "Among 8- to 18-year-olds, White youth spend less time playing video games in a typical day than other young people do (:56 for Whites, 1:25 for Blacks, 1:35 for Hispanics, and 1:37 for Asians)" (Rideout et al., 2011). Videogames are more than just another pastime: they are communicative platforms that are poorly understood by ratings agencies like the ESRB, either maligned or lauded by journalistic news media and pundits, and they are also public spaces where youth are negotiating their identities. The struggle for racial justice is occurring in gamespace as we speak. User-generated campaigns against in-game racism are one of many points of scholarly inquiry that can help us understand the purposes that hate speech serves for these communities of gamers who are increasingly "alone together," as Sherry Turkle observes (Turkle, 2011).

NOTES

- 1 While work such as Ivory et al. (2009) analyzes game content in order to trace the ways that game texts exclude the experiences of people of color and women, most studies of racism in videogames have focused on racial content and themes within game texts. Anna Everett (2009), David Leonard (2006), Jessica Langer (2008), Tanner Higgin (2009), David Columbia (2009), and Alexander Galloway (2007) have written excellent essays on racism in videogame imagery, narratives, and game mechanics. Representations of Black people as evil zombies, drug dealers, and criminals perpetuate some of the worst images found in other media, while the exclusion of images of Blackness from fantasy games creates an artificial "Blackless fantasy," as Higgin puts it. Racist representation within games can be found in every genre. Simulation games like the immensely popular *Civilization* series depict non-Western culture as shot through with superstition, cruelty, and irrationality (see Galloway, 2007). *World of Warcraft's* Tauren, Troll, and Blood and Night Elf player classes reprise classic racist imagery of Native Americans, Caribbeans, and Asians from previous media (see Langer, 2008). Interestingly, "casual" videogames that appeal to broad audiences like the 2009 "Game of the Year" *Plants Versus Zombies*, the classics *Tetris* and *Bejeweled*, the sidescroller *Braid*, and the beautiful *Passage* all lack this type of racial stereotyping.

- 2 The “dickwolves” discussion thread is an example of problems with sexism in the gaming community. Penny Arcade, a website that caters to gamers and sponsors a major games conference called PAX, published a cartoon entitled “the Sixth Slave” that used the word “rape” in a way that many readers found offensive. Feminist gamers and the Penny Arcade leadership waged a public flamewar over this use of sexist language, one that continued unresolved for several weeks. In 2011, many feminist gamers boycotted the PAX conference in protest at the organization’s handling of this controversy.
- 3 See Juul (2009) for an excellent introduction to the shift from hardcore to casual games.
- 4 Everett and Watkins (2008) have termed these types of spaces “Racialized Pedagogical Zones” in order to highlight their role in teaching young gamers about the proper place for raced and criminalized bodies (pp. 141–166).
- 5 See Everett and Watkins (2008) for an excellent example of this type of work.

From “The Ultimate Display” to “The Ultimate Skinner Box”

Virtual Reality and the Future of Psychotherapy

Marisa Brandt

ABSTRACT

Though most virtual reality (VR) enthusiasts of the 1980s and 1990s now concede that the technology was overhyped, a new group of advocates believes it has found a practical use for it: as a tool for conducting psychotherapy for post-traumatic stress disorder (PTSD) and other mental health problems. Marisa Brandt argues that the use of VR as a therapeutic tool is premised on a way of thinking about how to intervene in disordered subjectivity using media – what she calls *cybertherapeutic reason*. In this chapter, Brandt gives a brief history of how early innovators discovered the therapeutic potential of VR and implemented cybertherapeutic reason by designing controllable virtual experiences. She then compares three proposed systems for treating combat-related PTSD to show how the design of VR therapy systems can reflect diverse understandings of how the technology could intervene in subjectivity. Finally, she suggests some of the ways that widespread adoption of VR may affect the practice of psychotherapy.

Albert “Skip” Rizzo: Whereas in the mid-90’s VR was generally seen as “a hammer looking for a nail,” it soon became apparent to some scientists in both the engineering and clinical communities that VR could bring something to clinical care that wasn’t possible before its advent. [. . .] The capacity of VR technology to create controllable,

multisensory, interactive 3D stimulus environments, within which human behavior could be motivated and measured, offered clinical assessment and treatment options that were not possible using traditional methods.

(Rizzo et al., 2010, p. 117)

Psychology is the physics of virtual reality.

(William Bricken, quoted in Barlow et al., 1990)

Introduction: Cybertherapeutic Reason

The scene in the virtual desert takes up my entire field of view. If I look up, I see my gunner. Behind him peeks blue sky. Looking down, I see what I recognize as “my” masculine arm (though it is not attached to me) clothed in a sleeve of digital camouflage, gripping the steering wheel of a Humvee. To my right, my passenger, a racially ambiguous soldier character, is nodding and shifting weight just enough to give him some ersatz liveliness. Before me lies the flat gray road, mostly barren, some blocky architectural structures in the distance, and straight ahead another Humvee in the convoy. As I press the thumb controller button, we coast along the virtual desert. A sniper fires from an overpass. Cracks appear on the windshield and my passenger, digital blood on his fatigues, doubles in pain. I press onward, past stopped cars. “Are you ready?” asks the researcher. I nod. *Click*. The Humvee ahead of me explodes, and the base-shaker under my chair and the controller in my hand shake while black smoke fills the goggle screens.

For now, this kind of scene is recognizable from playing a videogame or even participating in a military training program. But instead, imagine – as I was asked to do, during the demo at a Southern California-based interactive media laboratory – that this could be part of a scene of psychotherapy. Therapy using virtual reality (VR) is one of the most well-publicized innovations in treatment for post-traumatic stress disorder (PTSD) among service members returning from the wars in Iraq and Afghanistan. I came to the media laboratory, as many journalists, military funders, interested clinicians, and technology innovators do, to experience this technology for myself and to learn why its advocates believed that experiencing a virtual version of Iraq could be therapeutic for men and women traumatized by combat. Why were so many so hopeful about the therapeutic possibilities of VR?

Advocates believe that the benefits of VR to therapy are twofold. First, they give cultural reasons, arguing that VR could encourage people to try therapy who otherwise might not, especially the newest population of young, male service members who might view talk therapy with stigma, but who in all likelihood have some experience playing videogames. Some VR therapy innovators have argued that patients who grew up in the “digital generation” are used to using digital media in order to communicate with friends and family, and so will be more comfortable interacting with virtual environments than merely talking with a therapist.¹ Advocates also give

technical and professional reasons, arguing that conducting therapy in virtual environments will enable therapists to provide controlled therapeutic experiences that will improve the efficacy of care based on exposure therapy. Exposure therapy is an empirically supported treatment for PTSD in which the patient revisits traumatic experiences in order to move past them. Given that problems including homelessness, alcoholism, unemployment, and domestic abuse are all associated with PTSD, providing efficacious care is seen not only as an important ethical issue, but also as a problem of governance and social integration for a new population of veterans from Afghanistan and Iraq, returning to the United States with signs of PTSD.

Like innovations in training technology, VR therapy relies on a view of non-technologically mediated, face-to-face communication as insufficient to the task of remaking selves. Training simulators, such as those used in aviation, medical education, and military training, utilize interactive graphic interfaces to help transform novices into experts by making training more engaging and concrete than traditional instruction. In the case of VR therapy, the hope is that interactive technology will provide experiences that will help transform mentally disordered people into healthy ones.

The integration of new media technologies into psychotherapeutic practice represents an important development in the techniques of self-making. Therapy is a key site of the practices of modern self-identity construction (see Giddens, 1991). Psychotherapy is founded on a faith in the capacity to know and transform individuals according to rational principles. From psychoanalysis to self-help books to psychopharmacology, the psy disciplines have been looking for increasingly effective, efficient, and rationalized technologies for improving selves, often centered on an image of perfect mental health as a balance between self-knowledge, feelings of efficacy, and overall contentment with one's position in the world (see, e.g., Healy, 1997; Rose, 1996; Szasz, 1984).

Cognitive-behavioral psychology, of which exposure therapy is a product, is a branch of psychotherapy that treats human beings as a part of systems: the mind itself is imagined as a set of structures that process the world. Originating in the 1960s, this model of subjectivity is cybernetic, that is, constituted through the exchange of information between subjects and their environment. Cybernetic models of subjectivity are particularly conducive to seeing the person in mechanistic terms, as an information processing system, and therefore capable of being *reprogrammed*. Similarly, N. Katherine Hayles (1999) has shown that the experience of "reality" in VR is based on cybernetic principles of subjectivity. As Hayles explains, in the cybernetic view of subjectivity, from the perspective of the human sensorium the world is information. The subject experiences the information as a world, whether embedded in a material reality or a virtual one. By the 1980s, researchers began to develop technologies to present the sensorium with "virtual worlds" that could become a viable new site for human evolution (Hayles, 1999, pp. 13–14; see also Hillis, 1999). Virtual reality suggested that we could create an environment we liked, leaving "real life" behind. Cognitive behaviorism suggested that if we could change our way of thinking about our place in our environment, we could change ourselves.

Thus, while the use of VR in therapy seems ironic on the surface, advocates believe that virtual environments can be used to improve how subjects interact with the actual world. I use the term “cybertherapeutic reason” to describe the underlying rationale behind VR therapy: the belief that well-designed human–computer interaction can help therapists to cure mental illness.² I have adapted this concept from the anthropologist Andy Lakoff’s term “pharmaceutical reason,” which he defines as “the underlying rationale of drug intervention in the new biomedical psychiatry: that targeted drug treatment will restore the subject to a normal condition of cognition, affect, or volition” (Lakoff, 2005, p. 7). Cybertherapeutic reason underlies the development of new media technologies as therapeutic tools. Whereas drug treatments use specially designed molecules in order to fix malfunctioning physiological systems in order to improve psychological health, cybertherapeutic treatments entail sessions of human–computer interaction designed to improve overall psychological health. In addition to VR therapy, cybertherapeutic reason can be seen in the use of health-promoting videogames, smartphone-based expert system applications, and avatar therapy in virtual worlds (see Anthony, Merz, & Goss, 2010, for more examples). The cybertherapy movement represents an era of renewed faith in the field of *psychological* intervention, made possible by the affordances – and affordability – of new media technology.

The most important affordance of VR technology is the capacity to immerse patients in virtual environments, and the design of these systems reflects assumptions about what a healthy individual should be able to experience without problem. Journalists writing on VR therapy often note that the virtual environments appear cartoonish and unrealistic, while repeating advocates’ claim that, for those suffering from mental illness, the environment will trigger their problems and reveal them. In the logic of cybertherapeutic reason, the healthy and the unhealthy can be distinguished by how they experience the virtual space: the virtual environment is not a space apart from the user’s reality, but rather becomes a tool for assessing his or her health in the actual world. But no virtual environment can fully represent the world. Thus, the efficacy of VR as a tool of psychotherapy can only be assessed by its capacity to elicit “unhealthy” responses. The design of cybertherapeutic systems, therefore, can be seen as materializations of normative assumptions about healthy subjectivity. My own sense of calm within the virtual Humvee only serves to indicate that I am not the proper target of that VR therapy system: from the perspective of the system, I am a healthy psychological subject.

VR therapy does not refer to a single practice. It has been proposed as a tool to augment a wide variety of therapeutic styles. What they all have in common, however, is a belief that the combination of immersive stimuli and interaction with virtual environments can improve the effects of psychotherapy. I focus on two key points of comparison across VR therapy systems: (1) the conception of “realism” at play in the system design (that is, what kind of scenario the virtual environment represents and how it represents it); and (2) how the control-interfaces distribute agency over the objects and events in the virtual environment over the course of

therapy. These two factors – realism and control – are key components in the role that VR plays in therapy.³

Though VR has spent the past two decades as the prototypical image of technological hype, this does not mean that media studies should abandon VR as an object of study.⁴ While some see the collapse of the commercial VR industry in the 1990s as evidence of the technology's failure, VR therapy advocates believe, on the contrary, that the technology has finally come of age. Whether or not the therapy advocates are right, the current interest in VR as a therapeutic technology is worthy of critical attention, especially for scholars interested in how subjectivities are being imagined and reconfigured in the emerging media environment. Examining therapeutic applications of VR requires a departure from conventional ways that media studies has approached its objects of analysis, especially a movement away from content and discourse analysis and toward careful attention to complex interactions between technological change and human subjectivity. In this chapter, I show how VR therapy was discovered as a potential tool for psychotherapy, which features of VR came to be defined as therapeutically significant, and how design variations reveal diverse interpretations of how VR can be used to transform the self. Finally, I speculate about some of the ways in which VR therapy might eventually transform psychotherapeutic practice.

A Hammer Finds its Nail: A Brief History of VR Therapy

Because of its ability to create “other” realities, virtual reality has always had interesting implications for human psychology.⁵ VR uses computer-generated sense-stimulating technologies that give operators the subjective experience of being in a three-dimensional space. In order to create this effect, immersive VR entails four components: a computer with a graphics engine, software that presents the user with a first-person perspective on a virtual space, a tracking device that monitors the user's body movements, and user interface technologies. The technology has its roots in human–computer interaction research. The graphical user interface was conceived as a technique that would make computers user-friendly by representing the seemingly incomprehensible volumes of information stored in computer databases as visual-spatial graphics that users could interact with in a “naturalistic” way (e.g., Engelbart, 1999; Licklider, 1999). But innovators realized that VR need not only represent data; it could represent any kind of environment the computer could render and generate any sensation that interfaces could simulate. Most historians trace the history of VR to 1965, when then-Harvard graduate student and later ARPA research scientist Ivan Sutherland proposed “the ultimate display,” “a room within which the computer can control the existence of matter” (Sutherland, 1965, p. 3). Three years later, Sutherland created the Sword of Damocles, the first binocular

display with head-tracking (Sutherland, 1968). The heavy head-mounted display had to be secured to the ceiling in order to be worn (hence the name), but when it was, it created the illusion of three-dimensional geometric forms that could be viewed from multiple angles (Aukstankalnis, Blatner, & Roth, 1992).

Two decades passed before VR became practical enough to gain interest outside of research circles. In a 1986 interview in *Scientific American*, inventor and entrepreneur Jaron Lanier introduced the phrase “virtual reality”, only two years after *Time* magazine had heightened public awareness of the burgeoning digital age by declaring the personal computer the “Machine of the Year.” For some, VR meant that computers would allow us to create and explore worlds, expand our intelligence, and create culture-transcending “post-symbolic communication.” A flood of VR hype swept over US culture during the late 1980s and early 1990s, as technologists and journalists promised a future in which new interface technologies would revolutionize education, training, scientific research, art, and entertainment (e.g., Aukstankalnis et al., 1992; Heim, 1998; Lauria, 2001; Rheingold, 1991). Some media studies scholars viewed the virtual world as a site for struggle and resistance (e.g., Brook & Boal, 1995; Hillis, 1999; Markley, 1996), while a slate of science fiction films reflected cultural anxieties over the possibility of people getting lost in it, completely detached from reality and high on the power of virtual existence. In the film *Lawnmower Man* (Everett & Leonard, 1992), for example, a doctor uses VR to transform a simple-minded lawnmower driver named Jobe into a power-hungry virtual god with little connection to his former humanity. Along similar lines, a now-infamous *Wall Street Journal* article referred to VR as “electronic LSD” because of its capacity to create private, potentially mind-altering experiences (Zachary, 1990).

In retrospect, VR had very little impact on mental health in the early 1990s. The technology was far too expensive for most people to access, and it was only good at rendering simple architectural spaces and geometrical objects. But researchers found that users treated those virtual, if cartoonish, environments as real. The combination of audiovisual immersion, first-person perspective, and the ability to interact with the virtual environment created a feeling of being inside a mediated space, called “presence” (see Biocca, 1997). Presence allowed operators of VR systems to have “real” experiences. Early commentators often described the outsiders’ perspective on presence: watching people in VR goggles crawling around the floor or ducking in response to some object only they could see (e.g., Aukstankalnis et al., 1992; Rheingold, 1991).

The therapeutic potential of VR began to come to light in the early 1990s. On opposite sides of the country, researchers discovered that VR would not only be experienced as real, but it could produce very real anxiety. To some this came as a surprise: after all, even if it felt real, users knew that it was not *actually* real. At that time, relatively few people had tried VR, aside from researchers and some curious visitors to arcades and trade shows. These were the contexts in which researchers discovered the therapeutic potential of VR. In 1993, Dr. Ralph Lamson, a psychologist at Kaiser Permanente Medical Group in San Rafael, California, claimed to have

discovered “virtual therapy” while trying a demo of VR at a technology exhibition in San Jose (Lamson, 1997). Lamson discovered that the simulated experience of being in a tall building triggered his fear of heights. Reminding himself that he was in a safe environment allowed him to confront his fear, and, he told an *LA Times* journalist, he cured his acrophobia by the time he left the exhibit hall (Stevens, 1995). Shortly thereafter he began a VR exposure therapy study, immersing acrophobic patients in 30-minute session of VR. In the virtual environment, they began in a café, then could walk out a door which led to a patio, then to a bridge. Lamson found that for most, the environment felt real enough to trigger their anxiety, as it had felt for him: “‘Some people don’t want to go out the door at all,’ said Lamson. ‘When they do, they wobble, spread their arms for balance, shake, or cry,’ all while standing in the middle of his office” (Stevens, 1995). Monitoring heart rate and blood pressure and instructing them in self-calming techniques, Lamson encouraged his patients to continue. He reported great success with most patients.

Across the country, at Clark Atlanta University, a doctoral student in computer science named Max North and his colleagues discovered the therapeutic potential of VR through a serendipitous moment in 1992 (North, North, & Coble, 1996). North’s team was working on a flight simulator project, in collaboration with the US Army Research Laboratory and Boeing (Wiederhold, 2007, p. 163). A team member began to experience anxiety while working, and admitted that she suffered from fear of flying. North’s team decided to experiment in using VR to cure her aviophobia by conducting exposure therapy using the same technology.

As one of the first people to see the world through the lens of cybertherapeutic reason, North was eager to explore the extent to which it could be applied to other phobias and other anxiety disorders. His early efforts were instrumental in enlisting other experts in the field to come up with the proverbial “nail” for the VR hammer – that is, the types of mental maladies around which VR could be defined as a therapeutic technology. In late 1992, North approached well-known VR researcher Larry Hodges at his office at Georgia Tech and proposed using VR to treat fear of public speaking (Wiederhold, 2007, p. 82). Hodges rejected the idea because the available computers were not powerful enough to render people. Though he initially found the idea silly, his brother-in-law, an Army psychiatrist, convinced him otherwise. They discussed what the technology *could* do and, from there, independently came up with the idea of treating fear of heights (Wiederhold, 2007, p. 82). In 1995, they conducted the first clinical trial of VR therapy with the help of Dr. Barbara Rothbaum, a clinical psychologist with expertise in exposure therapy working at nearby Emory. By 1996, Hodges and Rothbaum started a company, Virtually Better, Inc., to develop VR applications for a range of anxiety disorders, starting with specific phobias that were easy to model with virtual architecture, such as driving, heights, dark rooms, and open spaces. As VR technology improved, researchers eventually became able to populate virtual environments with digital human avatars, such as the passenger in my Humvee. In turn, the use of virtual human agents allowed virtual healers to begin treating more socially complex phobias, such as public speaking and being in

public spaces (North et al., 1996, Wiederhold, 2004). Therapists also began experimenting with mixed reality, for example, incorporating haptic technologies that allow arachnophobics to touch virtual spiders. September 11, 2001, also proved important for virtual reality therapy, producing an increasing interest in treatments for fear of flying, exacerbated by security restrictions that would prevent therapists from entering airports with clients, as well as the development of a virtual World Trade Center disaster exposure therapy study (Difede, Cukor, Patt, Giosan, & Hoffman, 2006).

The Ultimate Skinner Box?

Although the clinical value of VR has seemed to lay in its ability to simulate the real, the emphasis in the design of VR therapy systems is not recreating reality but, rather, creating the most therapeutic experiences within current technological limitations.⁶ Creating therapeutic environments entails conceiving of treatment in terms of changing how a patient responds to a given environment, but virtual environments can only ever be simplified models of the world. Some therapists refer to VR as the “ultimate Skinner box” because of its ability “to bring simulated elements from the outside world into the treatment setting and immerse patients in simulations that support the aims and mechanics of a specific therapeutic approach” (Rizzo et al., 2010, p. 116). The term “Skinner box” refers to the operant conditioning chamber, designed by US behaviorist B. F. Skinner. The chamber was a box or room that allowed the experimenter to control the physical stimuli presented to a subject, and pairing these with rewards and punishments in order to control behavior (see Rutherford, 2009). Therapists had been successful using exposure therapies to cure phobias for decades, directing patients to imagine or even confront fear-inducing objects and situations in order to overcome their fears. When adapting VR to the treatment of specific phobias, the issue of what to represent in the virtual environment is fairly straightforward. Virtual environments were designed to represent these feared objects and situations, and, as best possible, aimed to allow patients to interact with them as they might in real life: using a steering wheel controller to drive a virtual car, pressing the buttons in a virtual elevator, or approaching a virtual spider in a virtual kitchen.

As cybertherapists have begun to experiment with VR for the treatment of more complex disorders, the question of what to include in the virtual environment and how the patient should be allowed to interact with it has proven to be very open to interpretation. The tables of contents of the journal *CyberPsychology, Behavior, and Social Networking* (established in 1998) demonstrate that an ever-growing global community of researchers across theoretical perspectives is now experimenting with VR as a tool for conducting psychotherapy across the spectrum of mental health disorders, with very different ideas about the kind of reality it should be producing.

Especially outside of the United States, researchers have experimented with more diverse interpretations of how VR can intervene in subjectivity, using it to augment many kinds of therapy that employ imagination and simulated action (see Vincelli, 1999). For example, in the early 1990s, researchers at the Ojika Lab at Gifu University in Japan developed a form of sandbox play therapy for treating and diagnosing autism in children by observing how they play with figurines in virtual environments (Hirose, Kijima, Shirakawa, & Nihei, 1997). In addition, several groups of Korean researchers have experimented with using VR for role-play therapy for schizophrenics (Ku et al., 2003). The emphasis here is on immersing patients in common situations so they can learn how to effectively manage their symptoms in everyday life. Since the goal of treatment in this case is self-education about interpersonal effects of behavior, the design of these VR systems can focus more on “social realism” than on physical realism (Glantz, Rizzo, & Graap, 2003).

European researchers have experimented with using VR in experiential⁷ and psychodynamic therapy.⁸ The Italian psychologist Giuseppe Riva (2011) has used VR to treat eating disorders. In the environments he designs, patients see multiple models of their bodies, distorted to different proportions, in order to challenge their body image. They are encouraged to navigate virtual environments using different virtual bodies, in order to get a more realistic sense of how their actual bodies fit into the world. Here, the virtual is a site for producing experiences that the patient can contrast with reality outside of the goggles. Another Italian, Gabriele Optale, has used VR as therapy for erectile dysfunction, immersing patients in a world designed to engage them through symbolism. Patients visiting Dr. Optale’s clinic navigate a virtual forest with paths and obstacles they can overcome while a voice recording talks about childhood themes, drawn from psychoanalytic theories of sexual development. Optale believes that this unique therapy helps his patients to confront and conquer their impotence through symbolic experiences, without having to talk at length about their own personal sexual history (Optale, Marin, Pastore, Nasta, & Pianon, 2003).

This brief survey of international VR therapy demonstrates that despite a popular conception of VR as offering access to alien worlds, the emphasis of the design of VR therapy systems historically has been to create virtual environments that correspond to actual settings. The “realism” of VR therapy systems does not require that these settings precisely resemble specific situations or places in the patient’s actual life, but rather that it can create an evocative sense of presence for as many patients who struggle with that problem as possible. In the economy of design in VR therapy systems, reality is schematized, stripped down to an operationalized model of the world; in it, each element, be it physical or social, reflects an assumption about how to elicit and promote the control of unhealthy behavior. Designers’ belief that interacting with carefully schematized virtual environments can affect how a patient will interact with the actual world is the key component of cybertherapeutic reason. But variation among these systems reveals the diversity of opinions about how best to use existing VR technology to intervene in subjectivity.

VR for PTSD: A Comparative Approach

The use of VR in therapy for post-traumatic stress disorder offers important insights for understanding cybertherapeutic reason. Psychotherapy includes many approaches to intervening in traumatized subjectivity, only some of which are reflected in VR therapy for PTSD. In this section, I compare three VR therapy systems for PTSD treatment – two developed in the United States and one in the Netherlands. While each of the three systems uses a virtual environment to represent the scene of war, they vary in terms of the type of realism they employ and their form of user control. I emphasize these two elements for comparison: (1) the kind of “reality” the system is designed to produce and (2) how the control-interfaces distribute agency over the objects and events in the virtual environment during the course of therapy. These elements are an important basis for comparing different VR therapy systems because they reflect both differences in the way that designers think about the possibilities of using VR in exposure, and important variables available in the design of VR technology itself, “interactivity” and “vividness” being the two components of the medium that Jonathan Steuer argues determine users’ sense of presence (Steuer, 1992). Comparing these systems shows competing paradigms within the logic of cybertherapeutic reason regarding how VR should act as a psychotherapeutic tool.

By far the fastest-growing use of VR therapy is for the treatment of combat-related PTSD. In 2004, a widely cited *New England Journal of Medicine* report estimated that 11.2–17% of service members would develop PTSD as a direct result of fighting in the wars in Iraq and Afghanistan (Hoge et al., 2004). Subsequent reports have made even higher estimates. Because combat-related PTSD is notoriously difficult to treat compared to other forms of PTSD, the disorder has become a major focus for innovation in treatment. Hodges and Rothbaum conducted the first trials for treating combat-PTSD among Vietnam veterans in the late 1990s (Hodges, Rothbaum, & Alarcon, 1999; Rothbaum, Hodges, & Alarcon, 1999) with promising results. However, VR therapy for combat-PTSD did not receive a lot of public attention until 2005, when the US Office of Naval Research began funding the technique. Now VR therapy is lauded as a promising new paradigm for treating the current generation of veterans. In her editor’s introduction to the February 2010 special issue of *CyberPsychology, Behavior, and Social Networking* on PTSD, Brenda Wiederhold notes that two of the five top links retrieved by her Google search for “PTSD technology issues 2009” “addressed the value of virtual reality (VR) for PTSD” (Wiederhold, 2010, p. 1). The special issue itself is a testament to the practice: of the 13 studies published in the issue, 11 are studies of VR therapy for PTSD, each of which cites the efficacy of exposure therapy as a warrant for using VR.

On the surface, VR therapy for combat-PTSD can be seen as treating PTSD as a “war-phobia,” in that it is an acquired behavior, though it is more complex than a simple phobia because the fear itself is not irrational. Combat-PTSD is characterized by intrusive memories, nightmares, and hyper-arousal to stimuli associated with the

traumas of war-fighting. Uncontrollable anger and emotional numbing are also common responses. Sufferers often try to self-regulate through avoiding reminders of their trauma, which may manifest in behaviors such as reclusion, alcoholism, and insomnia. In their Virtual Vietnam experiment, Hodges and Rothbaum created virtual environments resembling the jungles of Vietnam and a virtual Huey helicopter that veterans could experience in order to overcome avoidance and confront the anxiety-provoking stimuli. These scenarios were chosen because they represented common experiences among Vietnam War veterans (Hodges et al., 1999, p. 11). As in the early VR therapy treatments for phobias, the authors justified their project using the language of cognitive behaviorism: repeated exposure to feared stimuli (in this case the war zone) would evoke the patient's fear response, leading to habituation and extinction (Hodges et al., 1999, p. 7). However, the design of the more recent generation of systems suggests more complex ways of thinking about the therapeutic use of VR for combat-PTSD.

VR-Enhanced Prolonged Exposure

Virtual Iraq/Afghanistan was developed by clinical psychology researcher Albert "Skip" Rizzo and engineering researcher Jarrell Pair at the University of Southern California's Institute for Creative Technologies. The current version of the system runs on one computer. The clinician views two screens, one displaying the patient's perspective, and the other a "Wizard of Oz" control panel displaying buttons that correspond to various locations and stimuli that can be added to the virtual environment. The patient wears a head-mounted display, stands or sits on a base-shaking platform during therapy, and receives audio stimuli through headphones. An optional scent-panel is also available to deliver evocative smells like gasoline and body odor.

Rizzo and Pair designed their system as a tool for conducting prolonged exposure therapy. In prolonged exposure, the therapist guides patients to retell the story of their trauma, each time adding more detail, and becoming increasingly emotionally engaged. Emotional engagement is seen as critical to the effectiveness of the treatment. They believe that by reliving the event, through telling the trauma narrative in the context of a safe environment, patients will not only come to dissociate the traumatic event from the feelings that give rise to their symptoms (a behavioral process), but will also become empowered by having transformed flashbacks – uncontrolled fragments of memory – into a coherent narrative (a cognitive one) (see also Losh, 2006).

VR is believed to aid in both remembering the narrative and becoming emotionally engaged. Like Virtual Vietnam, the Virtual Iraq/Afghanistan system was designed to include common scenes of action during deployment based on clinician feedback about frequently reported traumatic experiences. The designers also sent prototypes to Iraq and Ft. Lewis to get feedback on the realism of the representation. In the original version released in 2005, the virtual environments consist of a Middle Eastern

city and a Humvee, though new environments, including ones in Afghanistan and a Southwestern United States desert, are also being added. Though the technology enabled the designers to represent the most common scenarios of traumatic events, the design of these environments was limited by the capability of the available technology, which prevented the designers from making them as crowded, dirty, or able to be explored as thoroughly as they would have liked in order to make users' experiences more realistic.

Virtual Iraq/Afghanistan was designed with an emphasis on clinician control. The clinician chooses which environment to place patients in, as well as positioning them in various sites within that environment, such as making them the driver, passenger, or gunner of the Humvee. In the city scenario, they can teleport the patient from market to mosque to checkpoint or several other locations. With a push of a button, then can add the sounds of mosquitoes buzzing or a voice yelling, "Go home, cowboy." They can add or remove people from the streets, and blow up a surprising array of objects, especially parked vehicles. When these explosions take place, they can vary the "level of trauma," meaning how much damage the explosion does to people, from leaving people in the area a little dazed to having them lose body parts.

The patient can navigate the environment using either a standard videogame controller (for the Humvee module) or a thumb controller mounted on a weighted mock M-16 rifle (for the city environment). In current versions, patients can only navigate the virtual environment: they cannot shoot or otherwise effect change in the world. Even though firing a weapon is an important, and potentially among the most traumatic experiences of war, the designers were concerned about the value of surmounting the technical challenge of designing a realistic killing scenario that would not transform the simulation into a "cathartic revenge fantasy" rather than a therapeutic emotional processing session (Rizzo et al., 2010, p. 117). In a newer version, however, the therapist will be allowed to turn on the shooting function briefly.

Here, the clinician uses the machine in order to evoke emotions and memories from the patient. The patient, while immersed in the environment, is primarily active through storytelling rather than manipulating the interface. The virtual environment, controlled by the therapist, is designed to act upon the patient's psyche.

VR-Exposure with Arousal Control

This method was designed by Brenda K. Wiederhold and Dennis Wood of the Virtual Reality Medical Center (VRMC) in San Diego, California. There are many similarities between Virtual Iraq/Afghanistan and the system developed at VRMC. Like Virtual Iraq/Afghanistan, the VRMC clinician's interface includes a screen showing the patient's point of view and another showing the clinician's control panel. In both systems the therapist has a similar range of controls, and can teleport the patient around the virtual environment and add similar elements, such as shouting or

helicopters flying overhead. The virtual environments originally included a Virtual Baghdad, a Humvee scenario (which they call PTSD Convoy), and a “PTSD Village” (Wood, Wiederhold, & Spira, 2010, p. 5), though like the team at ICT, they are developing additional scenarios. Compared to the Virtual Iraq/Afghanistan system, VRMC’s patient interface engages fewer senses, entailing only VR goggles with built-in headphones.

While the technologies appear to share many similarities in their basic design, they differ in the degree of agency given the patient. The VRMC system uses a model of VR exposure developed by the organization’s founder, Brenda Wiederhold, in order to treat diverse anxiety disorders. The technique is called Virtual-Reality Exposure with Arousal Control (VRE-AC). Whereas Virtual Iraq/Afghanistan uses the system primarily to evoke memories and emotions to help the patients tell their trauma narratives, the VRMC system emphasizes “skills-building.” Though patients do tell the therapist about traumas they experienced, the therapeutic mechanism is not telling and retelling the trauma narrative. Instead, the therapist uses the biographical details in order to choose specific scenarios that patients will “play” during the course of therapy.

In VRE-AC applications, patients interact with the simulation in a manner similar to a videogame. Unlike the Virtual Iraq/Afghanistan system, patients not only can navigate the virtual environment, they can also use the controller to shoot an M-16 rifle (Wood et al., 2007, p. 311). Patients are given tasks, such as holding off insurgent fire while medics try to evacuate a fallen soldier, or driving their convoy to a specific location. Patients must do these tasks repeatedly. Realism is achieved both through virtual representation of spaces and through conducting the kinds of activities patients would actually conduct in the spaces represented.

VRE-AC environments are designed not only to trigger memories but also to actually allow patients to reenact traumatic scenarios in the simulation itself. Patients relive the trauma not through words but through actions. The emphasis here is on self-control. Before the VR session begins, the therapist teaches the patient meditation techniques in order to promote emotional, cognitive, and physical relaxation. During therapy, the patient is outfitted with physiological monitoring devices that measure skin conductance, finger temperature, respiration rate, and heart rate during therapy, which the therapist monitors on a third computer (Wood et al., 2007, p. 311). When the monitor indicates signs of physiological distress, the therapist draws the patient’s attention to how he or she is feeling and directs the patient to stay calm using the meditation techniques.

This method is seen as skills-building, emphasizing the patient’s ability to gain self-control through control over the situation at hand. Referring to her VRE-AC application for motor vehicle accident PTSD, Wiederhold says, “People who are afraid of the freeway say, ‘Oh my God, this is dangerous.’ I get them to stop the thought and think instead, ‘Yes, I’m sweating, but I’m still in control’” (Wiederhold, 2004, p. 43). The emphasis is not on making sense of the traumatic event but, rather, on learning to control one’s own mind and body when confronted with those kinds

of situations. As such, one learns how to confront reminders of the event that are both external and internal, such as memories. This model of agency is very different than the one invoked in the Virtual Iraq/Afghanistan system, which assumes that the patient will be healed through storytelling and habituation. By skills-building, the VRE-AC system deals with an important issue: what happens when the patient confronts another trauma, such as being redeployed to Afghanistan or Iraq?

Multi-Modal Memory Restructuring

A third system, designed by a team of researchers working at diverse institutions in the Netherlands, provides a helpful foil for comparing the Virtual Iraq/Afghanistan and VRE-AC systems. Unlike the other systems in which the world is ready-made with all possible scenes and elements already built into the software, in Multi-Modal Memory Restructuring (3MR) the patients actually build the virtual worlds. They are taught to use 3D editing software to reconstruct a specific day into a six-minute story. In addition to graphical elements built into the system, they can also use geographical maps as well as their own pictures, which are uploaded into the software. Also unlike the other systems, 3MR is based on the group-therapy exposure model, in which patients draw maps and other visual aids in order to facilitate talking about their experiences of war (van den Steen, Brinkman, Vermetten, & Neerincx, 2010, p. 208). The system uses a laptop computer and a projection screen rather than a head-mounted display in order to allow the group to work together.⁹ Using what they call a “situated cognitive engineering approach,” the Dutch team does not emphasize direct exposure but, rather, “time sequencing of the memory content,” that is, telling the narrative (van den Steen et al., 2010). The primary role of the therapist is to help the patients learn how to use the technology in order to help them tell stories.

Like Virtual Iraq/Afghanistan, the main purpose of the 3MR system is to enable the construction of a narrative in addition to exposure. The other systems are based on generic scenes and actions, achieving a kind of realism through reflecting the *designers’* understanding of the common experiences of war based on surveys of service members. In contrast, the 3MR system allows the group patients currently using the technology to achieve realism by working together and using their own photographs. The emphasis here is on recreating the collective memory by amalgamating individual memories and mementos associated with a particular day. Also unlike the other systems, 3MR encourages the patients to include positive memories related to the same deployment, which might otherwise be forgotten (van den Steen et al., 2010). Here, therapeutic exposure means not only confronting the traumatic event and reliving the fear associated with it in order to overcome it, but also exposing oneself to the emotional and experiential complexity of deployment.

Therapists using the other systems could also ask patients to consider positive feelings experienced during combat; however, those positive elements are not apparent in the design of either system. Though one might argue that patients can

successfully conduct missions in VRE-AC, this assumes that patients would necessarily experience these successes as positive experiences. The scientific journal articles and conference presentations promoting these technologies never address the possibility of using them to relive positive memories associated with deployment as one way to reframe their traumatic experiences.

Comparing VR Therapies

A comparison of these three therapies for PTSD demonstrates that VR therapy entails diverse strategies for mediating interaction between patient, therapist, and machine. It is not a matter of simply immersing patients in a virtual environment and having them emerge healed, but rather of a system designed to control the patient's experience within a therapeutic paradigm. All psychotherapies entail a model of how thoughts, emotions, physical feelings, and behaviors influence one another. But not all psychotherapists agree on how to intervene in these relationships. In some interventions, such as cognitive processing therapy, changing thought patterns is seen as a route to calming bodily feelings of anxiety. In others, such as the flooding technique for treating phobias, triggering emotions and physical experiences of fear in the absence of actual harm is believed to eventually retrain the mind.

At issue in these different interventions are questions of agency and control: what needs to be controlled and who needs to have control over it? Therapeutic rationale informs the design of VR therapy systems including how the virtual environment represents experience and how the ability to interact with it is distributed between the patient and therapist as distinct "users" of these systems. Understanding how cybertherapeutic reason plays out in VR therapy systems entails analyzing not only what they represent, but also the distribution of agency between the patient, therapist, and machine.

In VR therapy, agency over the virtual world is usually distributed unequally between the therapist and the patient. Control variables include who may choose which virtual environment the patient enters and what objects are present in that world. The goal is to train patients to respond to and understand their environment in different ways. For example, in Virtual Iraq/Afghanistan, patients are effectively learning that their traumas were things that happened to them, and that their only recourse is to face and learn to speak about them until they become like any other memory. The system reinforces this interpretation by giving most of the control over what happens in the external world to the therapist. In the VRE-AC system, by contrast, patients are treated more as active agents who must calm themselves in order to complete tasks: the trauma is not in the event *per se*, but rather in how patients respond to it. In 3MR, the group of patients is seen as a collective who use the virtual environment in order to create a multi-authored text representing their shared experience. They, too, are active agents in constructing how they remember an experience

and realize through diverse perspectives that they have options other than interpreting the event as a trauma.

In the VR therapy community, one of the most important contributions of VR is its capacity to create “real” experience. But as we have seen, what counts as realism varies greatly. It may entail objectivized realism based on physical characteristics of the environment, a procedural realism based on actions, or a personalized realism based on recreating specific events, or some combination of these. The goal of realism in VR therapy is to partially shift representations of the world from the patient’s imagination or the world itself, into a technological system. It becomes an individual experience through interactive processes such as the imagination, game-like interaction, or actually uploading personal images.

Whereas in traditional therapy the therapist cannot know for certain what is going on in the patient’s mind, in VR, the external, controllable simulation comes to stand in for internal mental life. While the virtual is often contrasted with the material or the actual, in virtual reality, the digital representation of the world can be seen as a materialization of the patient’s imagination: the digital representations, though merely light and sounds, are far more material than the imagination when it comes to the interaction of clinician and patient. Because the therapist sees what the patient sees (Gorini & Riva, 2008), VR therapists believe this can foster a common experience, perhaps contributing to therapeutic rapport. The therapist can instead ask for the terms that the patient uses for the objects, people, or places represented in the virtual world (Wood et al., 2010).

Objectivizing the patient’s experience through VR also frees the therapist from some of the work of stimulating the patient’s imagination. Being able to do so is seen in mental healthcare communities as a product of a good therapeutic alliance: the patient will only be able to generate useful mental images when he or she is comfortable with the therapist in the clinic. The challenge of building therapeutic alliance can be exacerbated when the therapist comes from a very different demographic than the patient population and does not have shared experiences to draw upon to help build mental imagery. After all, in most situations it would be socially inappropriate to disengage with the present and act upon one’s imagination, especially when talking about a scenario with which one’s interlocutor is completely unfamiliar. In VR therapy, the presence of the technology not only legitimizes the patient’s mental transportation to an alternate psychological space, but it also structures this experience within the parameters of what the therapist believes the patient should be imagining. The virtual environment is designed to already “know” what the patient needs to experience in therapy, whether it is reliving a combat scene in Iraq or just being on a tall building. However, as many scientific articles on VR therapy argue, even when there is good therapeutic alliance, some patients, it is believed, have poor visual imagination, do not like to communicate through speech, and avoid dealing with emotional difficulties. As such, VR can be a powerful tool for clinicians when the patient either cannot or does not want to do what clinicians believe would be therapeutically effective.

Objectivizing patient experience can also have implications for the politics of subjectivity. Though the VR hype of the 1980s and 1990s promised an unlimited world of virtual exploration, virtual environments are closed systems, wherein both the world and actions within it are constrained by software code. While the software does not arbitrate what counts as a psychological problem, its design does reify what does and does not count as a normal response to it. Though some aspects of the design may be limited by current technological capabilities – such as the capacity to render compelling human forms – design can serve to reify concepts of normalcy by deciding, *a priori*, what is and is not a “normal” response. For example, in the VRE-AC system, the design of the technology makes an implicit argument that the “healthy” response to being shot at or being ordered to shoot someone is to control oneself. As such, VR can be used to materialize conceptions of healthy subjectivity within the context of therapy, while at the same time reducing the capacity of patients to resist turning over their imagination or emotions to therapeutic control. The artifacts have politics: they materialize an ideal, in this case, an ideal model of healthy subjectivity and self-control.

Conclusion: The Future of Therapy?

By 1996, Max North and colleagues were declaring virtual reality therapy a new paradigm in clinical care. With slightly more modesty, Kalman Glantz and colleagues noted that “VR technology may create enough capabilities to profoundly influence the shape of therapy” (Glantz, Durlach, Barnett, & Aviles, 1997, p. 92). As we have seen, the capacity to generate controlled, disorder-specific immersive experiences, all within the safe and confidential setting of a clinician’s office, is the key technological contribution of VR to therapy. After years of being considered hype, VR is now being seriously considered as a therapeutic tool because it combines a kind of realism and controlled interaction that allow for the production of therapeutic experiences, based on a way of thinking about human–technology relationships that I call cybertherapeutic reason.

While VR therapy innovators are careful to insist that the computer is simply one more tool at the disposition of the healing profession, nevertheless, tools transform practices. If widely adopted, it will be important to document how VR changes the field of psychotherapy. It is possible to imagine a not-too-distant future in which therapists are no longer trained to use speech communication in order to elicit mental imagery, instead shifting the burden of this therapeutic skill onto technological systems like VR. Clinical psychology researchers currently debate the importance of “clinician effects,” by which they mean the difficulty of measuring the therapeutic efficacy of a specific paradigm because of the varying skill level of individual clinicians. VR therapy introduces the possibility of “software effects,” in which variations in therapeutic efficacy are attributed to the design or version of the software itself,

including the existence of “bugs” or interface usability issues. Widespread adoption of therapeutic technologies such as VR has the potential to shift at least some of the responsibility for therapeutic efficacy from therapist to the computer. On the flip side, an individual therapist’s lack of therapeutic efficacy may come to be seen as an issue of technical competency, one that can be addressed not only by improving his or her face-to-face rapport with patients, but also by outfitting the therapist with the most cutting-edge technologies and the skills to use them.

We are just reaching a time in which the number of people who will have visited virtual environments as part of treatment in a clinic will surpass the number of those who have done so during a demo at a research site. While the vast majority of clinicians do not currently utilize VR in their regular practice, this may soon change. In a poll asking American Psychiatry Association members about which inventions they expected to see increase in influence in psychology in the next 10 years, VR was predicted as number 3 out of 38 (Norcross, Hedges, & Prochaska, 2002).

The field has, indeed, been growing. Virtual healers have formed a research community, convening at an annual conference, Cybertherapy, which has grown in attendance and length since it began in 1996, and establishing numerous journals including *CyberPsychology, Behavior, and Social Networking* (est. 1998), *Annual Review of Cybertherapy and Telemedicine* (2003), *Cyberpsychology* (2007), *Journal of Cybertherapy and Rehabilitation* (2008), and *PsychNology* (2008). These forums have allowed virtual therapists to create a knowledge base for further research and field development. At the same time, the cost of buying and designing VR technologies has been dropping rapidly in the past decade, making these techniques increasingly accessible.

In recent years, powerful institutions, including branches of the United States military and Department of Veterans Affairs, have begun to express interest in VR therapy because it promises better therapeutic efficacy for treating PTSD, especially among members of the digital generation who are believed to be both comfortable with and attracted to interactive media technology. Further research is needed to examine the uses of VR therapy by these agencies, including the specific design of the VR systems they adopt. Doing so will provide new insights into how disordered subjectivity is defined, and how therapeutic interventions are conceptualized, as part of cybertherapeutic regimes. It is critical to examine how these institutions are coming to view the role of VR technology in reshaping the ways people interact with the world, and in the case of treating PTSD, how those afflicted communicate about, process, and heal from the traumatic experiences that now inform their lives.

NOTES

- 1 I distinguish between a *virtual environment*, or *virtual architecture*, and *virtual worlds*. Using Boellstorff’s (2008) definitions, virtual worlds are populated, persistent spaces, such as massively multi-player online games (MMOGs), that can be studied as fields of social action. “Virtual environment” refers to any interactive simulated space.

- 2 There is no set term for the practice. I primarily use the term “virtual reality therapy” (VR therapy), coined by Max North and colleagues (1996), though others believe this sounds as though the technology autonomously provides care. Ralph Lamson called it “virtual therapy” (e.g., Lamson, 1997), though this implies that it is not “actually” therapy. It has also been called “virtual reality-enhanced therapy.”
- 3 Though the issue of attraction to technology is also important, I will not be addressing this issue here as it concerns how VR creates new *meanings* for therapy, rather than what it does in cybertherapeutic practice.
- 4 The full title of techno-evangelist Howard Rheingold’s book on VR nicely sums up cultural ambivalence about where the technology would lead society: *Virtual Reality: The Revolutionary Technology of Computer-Generated Artificial Worlds – and How It Promises and Threatens to Transform Business and Society* (1991). Members of the field were also conscious of this ambivalence: the first SIGGRAPH panel on VR in 1990 was titled *Hip, Hype and Hope – The Three Faces of Virtual Worlds*. Woolley (1992) and Chesher (1993) have documented the VR of hype of the 1980s and 1990s. See Laurel (1993) on the collapse of commercial VR.
- 5 In the 1980s, both computers and postmodernism were transforming how people see the world. VR seemed to confirm the postmodern theories of the fluidity of subjectivity; if subjectivity is shaped by symbolic orders, then perhaps there is no one true reality and all realities are, in fact, virtual. See Lyotard (1984) and critique by Woolley (1992).
- 6 Because of high development cost and the slow process of clinical testing, VR therapy software often looks outdated compared to contemporary videogames. Advocates have suggested, however, that this is not a limitation but actually a *feature* of VR therapy, because visual simplicity leaves room for the patient’s imagination to project onto the virtual environment, thereby personalizing the experience (e.g., Hollander, 2006; North et al., 1996).
- 7 Experiential therapists believe that experiences can expose and challenge patients’ unconscious assumptions about the world and themselves.
- 8 Psychodynamic therapy also helps to reveal the unconscious to the patient by revealing origins of assumptions and challenging their role as patients’ unhealthy coping mechanisms.
- 9 As of this writing, the 1980s dream of networked, interactive immersive environments is still too technically complex and expensive to be a functional way to conduct group VR therapy.

Mapping ICT Adoption among Latin American Youth

Rosalía Winocur and Carolina Aguerre

ABSTRACT

In this chapter, Rosalía Winocur and Carolina Aguerre show how virtual communities and online social networks have been legitimized as new forms of visibility, recognition, and social inclusion among young people in Latin America. “To be or not to be part of something” and to be accepted or rejected for “forming or not forming a part of it” are core themes in the process of identity construction among Latin American youth, both online and offline. Faced with the difficulties of inclusion in the traditional institutions – particularly those related to training, employment, and access to power – young people adopt information and communication technologies (ICTs) in order to create alternative avenues to inclusion. The authors suggest that, by developing flexible and mobile strategies of ICT use and generating their own informal circuits of inclusion at the margins, young people may find avenues to gain access to the formal channels and privileged spaces of ICTs. In short, this chapter argues that Internet and mobile platforms are compensatory symbolic substitutes for the lack of real power these young people have in everyday life.

Introduction

The emergence and dissemination of information and communication technologies (ICTs) during the last two decades has promoted the expression “information society”

The International Encyclopedia of Media Studies, First Edition.

to characterize this age. In Latin America, as in most developing regions, the uptake and benefits of new ICTs have followed a much slower pace than in developed regions. This continent, which has a tradition of inequality, poverty, and profound cultural differences, has encountered difficulties not just in adopting ICTs but also in making them available and at the service of the most vulnerable sectors of society. Among those who have suffered the most from this exclusion are young people, in terms of opportunity costs, since youth have been one of the primary targets of the hopes invested in ICTs as a motor of development. “New digital technologies are now the depositories of a renewed hope that technology will drive economic development and fight poverty” (Guerra, Hilbert, Jordán, & Nicolai, 2007, p. 31).

Despite the economic growth evidenced in the region since 2002, together with public policies focused on lowering poverty levels by 17% and reducing the gap between rich and poor (Puryear & Malloy, 2009), it is still a region of contrasts. Latin America is the most unequal area in the world in terms of the gap between rich and poor, followed by sub-Saharan Africa. Five of the ten most unequal countries in the world are in this region, although Brazil is one of these and accounts for a third of the region’s total population. Even the most equitable countries in Latin America and the Caribbean, such as Chile, Barbados, Uruguay, and Costa Rica, have a higher GINI Index than the most unequal countries in Europe (Puryear & Malloy, 2009). In terms of poverty, 46.1% of the population in Latin America was poor in 2008, with 33.2% defined as “poor” and 12.9% as “extremely poor” (ECLAC, 2008).

The use and incorporation of technology in a society are not independent of its social, cultural, and economic context. The scenario described above means the region faces challenges to address the digital gap. In response to these disadvantages, which have affected the incorporation of Latin American states into the global economy, governments have begun the work of narrowing the digital divide by designing and implementing policies for digital inclusion. The United Nations’ Economic Commission for Latin America and the Caribbean (ECLAC) has incorporated ICT into its development agenda through the creation of the *Plan de Acción sobre la Sociedad de Información de América Latina y el Caribe* (eLAC, Action Plan for the Information Society of Latin America and the Caribbean). This initiative proposed building a platform to promote regional cooperation and integration of ICTs and articulating its goals on an international level, but with regional priorities. The Millennium Development Goals, the first of which is to eradicate extreme poverty by 2015, are on the eLAC’s action horizon.¹

In spite of the efforts that governments in the region have already made in terms of ICT inclusion, these policies and programs have had a varied focus and unequal outcomes. Many of these programs have been implemented recently, which means that their evaluation has not yet been undertaken in some cases and the longer-term impact is yet to be assessed. In this chapter we examine the underlying social, cultural, and economic context of ICT adoption by children and adolescents and their patterns of use, based on the results of quantitative and qualitative studies. An important caveat is that this work does not pretend to encompass all the programs and

initiatives, or to cover all patterns of use of ICTs in the continent, but instead analyzes major trends of adoption following certain sociodemographic variables and cultural attributes, according to the available data.

Quantitative Dimensions of ICT Access and Use in the Region

Evaluating ICT access in Latin America and the Caribbean (LAC) presents multiple challenges. Initiatives like those of the *Observatorio para la Sociedad de Información de Latinoamérica y el Caribe* (OSILAC, Observatory for the Information Society in Latin America and the Caribbean), particularly from 2007 to 2008, as well as the statistics team at the International Telecommunications Union (ITU), have attempted to harmonize and systematize data for the region. These projects are beginning to generate a greater uniformity amongst variables, including surveys and data-collection techniques. Nevertheless, data limitations restrict the ability to reach definitive conclusions about the impact of socioeconomic variables on the penetration and use of ICTs in Latin America and the Caribbean.

These difficulties stem from various causes. First, not all of the countries in the region have gathered statistics on ICTs, despite the fact that initiatives like those put forward by OSILAC and the ITU have established grounds for comparison. Second, the years in which surveys were completed vary from country to country. Another distinction is related to socioeconomic characteristics, which are also not homogeneous across the region. Finally, the rate at which technological changes are adopted can lead to outdated statistics; a piece of data only a few years old can quickly become obsolete (Sunkel, 2006).² Thus, comparisons can be challenging and inconclusive.

Despite these limitations, it is critically important to use the available data so that the social determinants of ICTs can be evaluated and major challenges – such as widespread access – can be addressed. In what follows, we present some important trends with respect to ICT access in Latin American homes, also identified in studies by Sunkel (2006), Hopenhayn and Miranda (CEPAL, 2004), and Minges and Olaya (2008). We have made efforts to include the greatest number of countries in the quantitative analysis, but the aforementioned restrictions in the existing databases and statistics, added to the large number of countries that comprise the region, make it practically impossible to cover them consistently with the same variables and analytic dimensions.

A salient feature is that in Latin America, traditional media predominate over “new” ICTs. Latin American homes are less likely to have access to ICTs than to traditional media such as radio and television. This is especially troubling given that the penetration of television and radio in the region is already poor in comparison with developed countries (Mastrini & Becerra, 2006). Mobile phones are an exception, as they have surpassed landlines in various regions on the continent and within each country (see Table 23.1).

Table 23.1 Percentage of ICT access in the home, by type of technology

Country	Year	% of households with						Type of Internet access	
		Electricity	Radio	Television	Land line	Cellular phone	Computer	Internet access

The largest impact on the availability of ICTs in the home is income, followed by years of education completed by the head of household. ICT penetration in homes grows proportionally to these two variables. As Table 23.2 shows, there is a strong correlation between the head of household's education level and home ICT access. The largest leap is in those who have completed secondary to higher education, or incomplete technical education, in all of the countries analyzed.

These data indicate that the tendency to value ICT access positively is related to a higher level of education. However, this relation is strengthened when one takes into consideration that throughout Latin America there is a strong correlation between education level and socioeconomic level. People with a higher level of education are more likely to have a higher income than those with a lower degree of education and thus are in a position to afford the cost of home ICT access (Programa de las Naciones Unidas para el Desarrollo [UNDP], 2006). The data presented in Table 23.3 support this interpretation. In the case of household income level, it is worth noting the leap in the fourth quintile, which is close to doubling in the cases of Brazil and Mexico, nearly trebling in Colombia, and more than trebling in Peru and El Salvador. The greatest difference between the fourth and fifth quintile is registered in El Salvador, Peru, and Mexico.

This trend can also be seen in other countries in the region. Urresti (2009) shows that in Argentina in the 1990s, the middle and upper socioeconomic sectors were early adopters of new technologies, which increased the levels of demand in both homes and businesses for more computers and greater Internet access, particularly in the city of Buenos Aires. Therefore, in Latin America the rates of access to technological goods and connectivity in various districts within cities like Buenos Aires, San Pablo, Mexico City, or Santiago have been comparable to cities in Europe or the

United States. However, these relatively high rates of connectivity are much lower in small cities and towns, and more so in rural environments. In this sense, ICT adoption follows the same trend in terms of access as those of traditional media and other services (such as sewage, electricity), discriminating positively for the inhabitants of cities and negatively for semi-rural or rural environments that face greater challenges and gaps.

Nevertheless, this early and high rate of adoption by urban social sectors of a higher socioeconomic level produced a “trickle-down” effect in these cities. This was the case, for example, in Buenos Aires (Urresti, 2009), which generated a second wave of access in the information hubs, where the first public-access technology centers were opened at the end of the 1990s. This trickle-down effect was produced primarily by the lower costs of personal computers (PCs) and the expansion of Internet connectivity in the city of Buenos Aires. From a sociocultural perspective it followed a pattern of imitation from the cosmopolitan rich sectors (including national and foreign firms) to the middle classes. The youth in these lower- to middle-class urban sectors were the first to use new technologies in these public centers.

A second notable trend concerns ICT access in households with children and youth. The presence of children is one of the most influential factors for the adoption of ICTs in a household (Barrantes, 2007; ITU, 2009). Thus, surveys should count not only the number of children but also their ages in order to establish links to educational institutions. The number of children is also a central variable, given that throughout the world two-child households tend to have consistently higher levels of ICT penetration in comparison with those that do not have children (ECLAC, 2008). The LAC region is no exception.

Nevertheless, among households with more than two children, the percentage drops, and in those domestic environments with more than four children, it is even lower than in those with no children. The lowest numbers of computers belong to

Figure 23.1 Percentage of households with a computer, by number of children in the household, 2005. *Source:* ECLAC (2008, p. 24).

households with more than five infants. The data supplied in Figure 23.1 express these differences across five countries in the region. These data reinforce the relationship between income levels and access to technology in the home. Households with more than four children tend to be low-income, while those with an average of two to three children are typically representative of middle- to upper-middle-class sectors.

A third trend concerns use of the mobile phone, a new technology that appears to be more resistant to inequality than other technologies. Table 23.4 shows GINI coefficients for ICT access in the home, providing a basis for evaluating disparities in access among different socioeconomic variables. The GINI coefficient is a useful statistical tool for measuring the distribution across diverse socioeconomic variables of ICT in the home. A GINI coefficient of zero represents perfect equality, while a coefficient of one represents the highest level of inequality.

The data in Table 23.4 offer a number of important findings about disparities in traditional and new media. The greatest disparity is found in Internet access, while radio reflects the smallest degree of disparity, being the most democratic medium (lowest GINI Index). Mobile telephones tend to show a more equal distribution than fixed-line telephones. Fixed telephone lines tend to correlate with gender, meaning that when the household head is a woman there is a tendency to have fixed landlines, while mobile phone possession depends on the number of years of formal education that the head of household has completed. The age of the head of household is central to determining the most equal distribution between television, computer, and Internet access. Indigenous groups correlate with a more equal access to the radio. In the context of the LAC region and in the majority of its countries, belonging to

Table 23.4 GINI coefficients of ICTs in the home

Indigenous group	Head of household								
	Gender	Age	Years of education	Employment category	Income	Electricity	Location ^a	Children	Average
Radio	0.14	0.25	0.18	0.28	0.18	0.30	0.15	0.65	<u>0.26</u>

^aRural/urban

Source: Adapted from OSILAC (2007).

an indigenous ethnic group is strongly related to rural as opposed to urban environments, and to lower as opposed to higher economic status.

The worst ICT distribution appears to be related to the number of children in the home, as has already been mentioned (and depicted in Figure 23.1). With five children, ICT penetration falls dramatically. Electricity is the second category that creates inequality, given that without this indispensable resource, there can be no access to television, much less to a computer. Even charging a mobile phone becomes difficult. Household income is the third inequality factor.

However, to consider the complete picture of media use among children and adolescents in Latin America, we must take into account the use of the mobile phone, a device that has become so ubiquitous that it is already beginning to take off as a platform for Internet access for the least developed countries in Latin America and the rest of the world (ITU, 2010a). It is worth noting that some developing countries, like Tanzania in Africa, already have greater email access via mobile phones than via computers (TNS Research International, 2010 Digital Life³), and Latin America with its higher than average mobile penetration (93%, when the world average is 73%) is already evidencing this transition to Internet access via mobile phones (ITU, 2010a). Nevertheless, although accessing the Internet through mobile phones is getting easier with each new generation of devices, it is still costly to connect given the expensive rates, and even more so for young people (Galperin & Barrantes, 2008) who tend to suffer more from unemployment – 16.6% unemployment rate amongst youth in the Latin American region, which is triple the adult rate of unemployment (Weller, 2006).⁴

According to a study of “The Interactive Generation in Ibero-America” (Fundación Telefónica, 2008)⁵ conducted in seven countries (Argentina, Brazil, Chile, Colombia, Mexico, Peru, and Venezuela), 86% of urban youth between 10 and 18 years of age own a mobile phone. The countries that lead this trend are Argentina (94%), Venezuela (93%), and Chile (93%). In terms of gender, girls prefer to use mobile phones more than boys (86% use amongst girls vs. 80% for boys). This study also found that communication is the most important use that the youth attach to mobile phones (80% use them for this purpose – SMS and calls), followed by the consumption of content (50% use them to listen to music, 47% to watch videos and look at photos, and 13% to access the Internet). A third use of the mobile phone is entertainment, while the creation of content (taking pictures and shooting videos: 50% and 45%, respectively) is a fourth use attached to this device by this age group. This research also points out that 33% of the youngsters have a mobile device as a present from their parents, who also pay for the monthly expenses in 63% of the cases.

Finally, the data on ICT access in Latin America reveal a hierarchy of access by country. According to the report *Characteristics of Households with ICTs in Latin America and the Caribbean* (OSILAC, 2007), there are three large groups in the region, organized by socioeconomic performance variables and access to ICTs in the home. The first group is composed of Brazil, Chile, Costa Rica, Mexico, and Uruguay.⁶ These countries have high levels of household ICT penetration for the region, and higher

than average performance in almost all of the rest of the socioeconomic variables. The second group consists of the countries that perform well in the socioeconomic variables but have less ICT penetration in the home. This is the case with the Dominican Republic, El Salvador, Paraguay, and Venezuela. The third group is made up of countries that have a below-average performance in socioeconomic variables and a low level of ICT penetration in the home. This group includes Bolivia, Guatemala, Honduras, Nicaragua, and Peru. Tables 23.2 and 23.3 show the differences between countries in these distinct groups, which underlines the point made in the introduction, that ICT access and adoption are closely dependent on other socioeconomic variables and cultural features.

The Indicators in Perspective: Regional Strategies and National Plans

Up to this point we have examined *household* sociodemographic indicators, but in the LAC region other data suggest that *collective* forms of access to ICTs are much more common than in the developed world (ITU, 2010b; Maeso & Hilbert, 2006).⁷ Nevertheless, data available on the types of collective access for children and youth in the region are still uncertain, beginning with the lack of information on ICT equipment, Internet connectivity, and the impact on users in educational institutions.

For example, in Brazil, with the PROINFO Program (which dates back to 1997), 19.6% of schools were connected to the Internet in 2004, covering 14.3% of students (Villatoro, 2009). In Costa Rica the Educational Computing Program (PIE MEP FOD) was benefiting 51% of students at preschool and elementary level and 72.8% at early secondary level in 2004 (Villatoro, 2009). In Uruguay, the CEIBAL project, the only one-to-one access program following the One Laptop Per Child (OLPC) initiative, accomplished in 2010 full coverage of the distribution of laptops to primary school children in state schools (which accounts for nearly 88% of all children – urban and rural – in the country) (Katzman & Rodríguez 2006; Martínez, Alonso, & Díaz, 2009).

While these programs were conceived under very different governments and societies, there is a common pattern: their objectives are associated with technology and its devices. ICT access in classrooms, for students and teachers, seems to be an increasingly central policy in these countries' educational plans. These programs differ from earlier projects that prioritized access to infrastructure in educational institutions (for example, the first years of the program *Enlaces* in Argentina, which started in 1999). Newer programs are now attempting to focus on technology and its uses, linking both content and types of work (on the network, with virtual platforms) as well as promoting mechanisms to bring people closer to knowledge and information. Another important aspect is the advance of the one-to-one access paradigm in educational realms, where programs like the *Plan CEIBAL* in Uruguay,

Programa Una Laptop por Niño (One Laptop per Child Program) in Peru, and *Conectar Igualdad* (Connect Equality) in Argentina are already palpable realities.

Public access centers that provide connectivity to communities have contributed to the weakening of poverty as a unique variable for digital inequalities when they are present with human capital, i.e., facilitators and trainers. This has proved a distinct feature of the Latin American region and has proved particularly successful in rural communities and smaller distant urban centers (ITU, 2010b). These spaces have adopted diverse institutional and organizational arrangements that represent the public sector (*telecentros*, or centers where the public can access computer technology), civil society (access centers and training within social organizations), and the private commercial sector (Internet cafés) (Maeso & Hilbert, 2006). These venues, as applied research in the region indicates (Maeso & Hilbert, 2006; Proenza, Bastidas-Buch, & Montero, 2001), play a substantial role in providing access to the Internet and computers for low- and middle-income sectors. The appearance of these public access centers throughout the entire Latin American subcontinent, predominantly in the last decade, is now a focal point for public policy on the subject of ICTs in Latin America.

The results shown in Table 23.5 examine the relationship between the use of the Internet and mobile phones amongst children and young people, ages 10 to 24, from various countries in the region. The data present some interesting trends. On the one hand, children and young people from 10 to 19 years of age use the Internet more, in comparison with those aged 20 to 24 years old. These figures decline as age increases, confirming that usage patterns of children and young people are usually much higher than for adults. In the case of Mexico, there is a greater distance in Internet use between the 20–24 cohort and the 10–14 and 15–19 groups, a factor that can probably be linked to young adults accessing technology at work, while children and adolescents depend on access via educational centers or public access points.

The educational uses of the Internet represent a low to very low percentage in all of the countries studied. This suggests an important challenge for education in terms of competing uses for the Internet – predominantly social, with informational uses in second place. The tendency toward the one-to-one model of connectivity in primary and secondary education in various countries of the region is an important challenge for the provision of educational activities and content in the online environment.

While Argentina has not been incorporated into the OSILAC database (an initiative carried out by the ECLAC), it has carried out a Cultural Consumption Survey (SNCC from the Spanish acronym),⁸ with the latest edition published in 2008, which provides relevant information about access to and use of ICTs in this country (see Tables 23.6 and 23.7). The regional survey “The Interactive Generation in Ibero-America” (Fundación Telefónica, 2008) presents a similar landscape to that presented by the SNCC survey in Argentina on the patterns of Internet use by children and young adults. The predominant use of Internet services by children from 10 to 18 years in seven countries corresponds to the “communication” dimension (first

Table 23.5 Young people's use of the Internet and cell phones

chatting and then email).⁹ Although the “knowledge” dimension is not directly related to the educational uses expressed in Table 23.5, it matches the data of the SNCC (2008) from Argentina (Tables 23.6 and 23.7), showing a growing trend toward incorporation of the Internet in the creation and acquisition of information and knowledge.

Qualitative Dimensions of ICT Access and Appropriation in the Region

Up to now this chapter has dealt with the macro-variables that have been most commonly used in studies of a quantitative nature in the region. Alongside efforts to measure the digital divide and the impact of government and international organizations’ programs of digital inclusion, Latin America has developed socio-anthropological, qualitative studies that seek to reconstruct the experience of ICT appropriation among diverse groups of children, adolescents, young adults, and teachers of different sociocultural realities. In spite of the studies’ isolated and dispersed nature, this line of research is very valuable because it sheds light on a number of phenomena that are difficult to measure, such as the emergence of social networks and virtual communities in the sociability of youth, the possibilities for accessing cultural and symbolic goods through networks of exchange, new knowledge that makes ICTs possible, and new forms of social inclusion and participation in the public

sphere. Most of this research questions the instrumental view and the underlying assumptions of ICT incorporation programs from a theoretical and methodological perspective, arguing that these programs uncritically assume the neutrality of technologies and the universality of their effects. In this sense, they show the need to investigate the processes of incorporation and the multiplicity of the social uses of technology on a local scale (Urresti, 2008; Winocur, 2009), recognizing that local contexts lead to different ways of appropriating ICTs. These different uses are expressed not only in classic socioeconomic variables (e.g., age, sex, education level, income) but in the collective experiments of social movements and neighborhood organizations, as in the case of the unemployed in Argentina (Winocur & Benitez Larghi, 2010), in the alternative circuits of cultural production that young people generate, and in the processes of migration or displacement of families or some of their members. In what follows, this section will cover some of the main research conducted through this cultural perspective.

Over the last 10 years, scholars have conducted a wealth of qualitative research on ICT appropriation by adolescents and young adults in Latin America.¹⁰ Studies were done in Argentina (Aliano, López, Welschinger Lascano, Stefoni, & Guevara, 2009; Aprea, 2002; Cabello, 2006; Finkelievich & Prince, 2007; Light, Manso, & Vilela, 2001; Urresti, 2008); Bolivia (Arratia, Uberhuaga, & García, 2006; Uberhuaga Candia, Arratia Jiménez, & García Miranda, 2005); Brazil (Godoy Gomes, 2002; Seabra, 2008); Colombia (Cabrera Paz, 2001; Jaramillo, 2005; Jaramillo Marín & Ruíz Quiroga, 2009); Mexico (Castro & Zepeda, 2004; López González, n.d.; Robinson, 2003; Winocur, 2006, 2009; Zermelo, Arellano, & Ramírez, 2005); Peru (Loyola, 2006); Venezuela (Quero Ramones & Madueños Madueños, 2006); Chile (Arancibia Herrera & Carrasco Herrera, 2006; Arredondo, Catalán, Montesinos, & Monsalve, 2001; Silva Peña, Borrero, Marchant, González, & Novoa, 2006; Soto Valenzuela, Espejo Silva, & Matute Willemssen, 2002; UNDP, 2006); and Spain (Albero, 2002; Espinar Ruiz & González Río, 2008; Feixa, 2005; Feixa, García, & Recio, 2004; Feliu, Gil, Gil, & Rivero, 2003; Gil Juárez & Vall-llovera Llovet, 2006; González Río, Espinar Ruiz, & Frau Marhuenda, 2007; Martínez Borda, Lacasa, & De Guzmán, 2008; Naval & Lara, 2003; Rodríguez Pascual, 2005, 2006). Among this body of qualitative research, we have identified eight general observations concerning youth ICT access in Latin America.

The Importance of Collective Access to ICTs

In the research contexts studied, access to computers and the Internet is generalized to all youth and adolescents, with no consideration of the social sector they come from, even though there is a “clear predominance of those who come from homes with more resources in respect to the quality of their connection and exposure time to the Internet” (Urresti, 2008).¹¹ In Mexico, according to the *Encuesta Nacional de Juventud 2005* (National Youth Survey, 2005), only 28% of those between 15 and 29

years of age had a computer in their home, although almost 70% (69.66%) know how to use one. With regards to the Internet, only 20% had a connection in their homes, although 60.75% know how to use it. In the case of mobile phones, only 56.5% have one, but almost 80% (79.95%) know how to use one.¹² Another relevant piece of information is that only 49.7% are in some type of formal education system. What do these figures tell us? In the case of youth, the adoption of new information and communication technologies does not depend fundamentally on having a computer or Internet connection at home. Often they have access in collective or public environments such as Internet cafés, schools, and universities. As previously mentioned, in various Latin American countries, including Mexico, the main sources of Internet socialization among youth between 15 and 19 years old are commercial venues with Internet access (OSILAC, 2007).

Cultural Capital as a Prerequisite for a Richer Appropriation of ICTs

Public universities, independent of the sociocultural origins of their students, are an exceptional environment for technological socialization, linked not only to curricular demands but also to university culture (Winocur, 2006). Nevertheless, Internet access does not guarantee equal opportunity to inform oneself, to belong, to debate, or even to play. The cultural and symbolic capital and the processes of technological socialization of young people from diverse socioeconomic backgrounds generate different contexts of cultural appropriation through the Internet:

Some young people, equipped with prior knowledge of the “media circuit” in which they move with fluency, come already skilled and prepared to navigate the web; in total fusion with the machine, they become the most skilled navigators. Other young people, and the majority of their teachers, get lost in the technological difficulty, lack of training in the technological sphere and, under-equipped with cultural capital, they sink quickly, easily, and with anguish. (Cabrera Paz, 2001, p. 40)

The Role of School and Friends

Various research efforts, carried out in very diverse sociocultural contexts, show that the first contact adolescents and young adults have with computers and the Internet, particularly in working-class sectors, is at school (Lizarazo, 2008; Urresti, 2008; Winocur, 2006). The first reference points for youth are school assignments, followed by games (Silva Peña et al., 2006; Soto Valenzuela et al., 2002). But the real socialization comes from friends and in informal spaces outside school, particularly in Internet cafés, which have proliferated in cities, or in community technology centers (Finquelievich & Prince, 2007; Robinson, 2003), as well as through initiatives implemented by civil organizations in rural and urban communities. Internet cafés

are not only spaces of initiation into the navigation and utilization of programs and web applications. They are recreational spaces for the socialization and exchange of technological knowledge (Arratia Jiménez et al., 2006; Castro & Zepeda, 2004; Gil Juárez & Vall-llovera Llovet, 2006; Linne, 2009).

The Sense of Belonging in Virtual Networks

The growing importance of ICTs in young people's personal, social, political, and academic lives has transformed the traditional nucleus of information and sociability. It has not necessarily replaced more traditional forms of socializing, but instead has amplified or modified them: "The Internet is not a substitute for life outside the screen. On the contrary, it forms part of a continuity that facilitates the satisfaction of individual needs and the cultivation of new interests, often with the attendant creation of collective social capital" (Katz & Rice, 2005, p. 351). In the same sense, in spite of the growing proliferation of networks and virtual communities among young people, there is nothing to suggest that they replace family ties, romantic relations, or groups of belonging (Katz & Rice, 2005; Wellman, Quan Haase, Witte, & Hampton, 2001; Winocur, 2006). More likely, they serve ideally to recreate affective and leisure spaces in crisis or to cover up unsatisfactory aspects of oneself. Virtual communities have much more relaxed mechanisms of inclusion and exclusion that allow youth to have a sense of belonging through technological and nomadic practices of constant identity reinvention. Thus the fundamental importance of these virtual networks and contacts does not reside so much in their capacity to multiply, or in their power to bring people together, as in the projection and validation of the needs of their members. What once was a form of exclusion here becomes a condition of belonging (Winocur, 2006). Other works examine the possibilities of cultural production associated with practices of ICT consumption among adolescents in leisure spaces (Arratia Jiménez et al., 2006; Feliu et al., 2003; Linne, 2009; UNDP, 2006).

The results are very suggestive about the role adults, parents, and educators play in the stigmatization of youth as a risk group. Especially noteworthy is the role of new technologies in the processes of interaction and relations that they themselves produce. This disrupts the image of the isolated and addicted adolescent, often referred to in the literature and the media, and instead shows how youngsters practice new ways of constructing a digital culture: meeting around ICTs. (Feliu et al., 2003)

Imaginaries on ICTs

For young people who have access to the Internet, particularly adolescents and university students, ICTs have become an imaginary universe that are particularly significant to their activities and relations. When they speak of what ICTs mean in their

personal lives, they describe them as spaces of information, contention, and communication, not with the whole world but with those who are truly important to them (Winocur, 2009). They mainly use the Internet to stay in contact with people they know – with whom they have strong affective ties in the real world (relatives that live far away, friends from high school, romantic partners). They also use the Internet to maintain intense everyday life relationships developed through teamwork, information exchange, or technological socialization in the office, at school, or at university (Espinar & González, 2008; Feixa et al., 2004). Much of what happens on the Internet becomes meaningful to young people when they can practice its benefits in the real world. Everything that you can get on the Internet – information, entertainment, technological competence, new relationships – is capitalized on and fundamentally validated in the world of personal relationships. Behind every act of virtual flirting hides a secret hope that it will become a concrete, flesh-and-blood relationship; the majority of emails are exchanged between people who already know each other or between academic peer communities. The bulk of the information they search for, consult, and download is used to broaden a comparative perspective for work and investigations in academic or scholarly circles where they meet face to face, or as a source of prestige and inclusion in social spaces with friends and colleagues (Winocur, 2006).

ICTs and Symbolic Power for Youth

The Internet is often the only source of effective power that young people have; although its efficacy is only symbolic, it is still relevant in their daily lives. This illusion of power is expressed and exercised in various ways. First, in the possibility of connection–disconnection; in other words, when they want to “be visible” and “invisible,” and for whom. Second, in the resource of “infinite” navigation that translates into the pleasure of discovering and conquering diverse, contrasting, strange, and disquieting worlds, without leaving the certainty of home and without running any major risks. Third, and fundamentally, in the manipulation of virtual reality: creating and destroying an empire in minutes in a game of strategy, invading a friend’s privacy by entering into his or her account; manipulating free software, designing a personal web page, creating a blog, or founding a community and imposing or censoring content, establishing the rules, and deciding who can be a part of it. As a consequence of this eagerness to “manipulate,” “conquer,” or “discover,” mainly what young people require and consume on the Internet is information. This includes information of all types and kinds, but what is prioritized, particularly in the case of males, is the web that they can spin around themselves through programs, using diverse tools and applications to create web pages, translating languages, mounting multimedia devices, and downloading music, movies, comics, and so on. In addition, they search, download, and edit information for the academic requirements of a variety of subjects. The majority use the most popular search engines, like Google, Yahoo, and Altavista, but some also read blogs or electronic magazines as well. They also

browse sites that advertise entertainment related to their tastes in film, music, and television. The consumption of information does not only have an instrumental value, in the sense of serving to support research projects assigned in the university, or to see what shows are playing; the fundamental value is symbolic (Cabrera Paz, 2001; Winocur, 2006). The web has everything that youth culture has made relevant and meaningful by showing and sharing it with others (Cabrera Paz, 2001). Until the early 1990s, film and television provided the basic symbolic material for conversation. Now, the Internet has not only considerably increased conversation topics, it has also changed the nature of that exchange – not only is information shared, but there are also new experiences of social interaction, competencies, and skills to manipulate on the Internet.

Youth Identity on the Internet

The way young people have incorporated the Internet into their lives, simultaneously entering and exiting online and offline worlds, suggests that participation in both has been integrated into contemporary daily experience, in the constant movement in and out of the domestic space, in different ways of being and inhabiting cities, and in distinct public and private, formal and informal environments: “Young people’s practices use resources in a combined way – formal and informal, legal and illegal – to fulfill their desire to connect, inform, and entertain each other and themselves” (García Canclini, 2006, p. 4). Young people represent the web as a space where everything can be looked at, without censorship. On the Internet, young people act like they do in the mall: they want to see and to be seen. The Internet is a space of affirmation of identity. It is perceived as a library that condenses all human knowledge. The Internet is present and instantaneous. For young people, it is a scene of pleasure. It is understood as a place where someone is always available to listen; thus, its use is connected to sociability, without limits or borders, and where the main focal point is shared interests (Cabrera Paz, 2001; Castro & Zepeda, 2004; Feixa, 2005; Feixa et al., 2004; Winocur, 2006). The recreational character of the navigation and utilization of available programs has substantially improved the capacity to increase information and knowledge about diverse historical, political, social, and cultural realities, but this does not necessarily result in a better ability to reflect on them. It has also been found that for working-class youth, the Internet does not play a large role in supporting the formal learning process because in most cases they do not have the skills to use search engines effectively (Arratia Jiménez et al., 2006).

Old and New Educational Practices

In many public schools, the incorporation of ICTs has not added value to learning; they are incorporated into the “old ways” of the classroom in a manner that sustains “old” teaching practices (Jaramillo Marín & Ruiz Quiroga, 2009). In the case of teach-

ers, the difficulty some have in using new technologies often provokes profound feelings of anxiety and insecurity because it directly questions their authority in front of the students.

Perhaps what is happening deep down is that computers and information networks in schools put relational structures (in other words, systems of power) at risk, because it seems clear that the student/teacher relations are radically resituated. The teacher in this new model becomes “decentralized” and with it, the whole thread of the traditional educational system. This empowers the possibility of “infant intellectual autonomy,” as cybernetic systems provide resources to students so that they can acquire and process knowledge with less teacher mediation. (Lizarazo, 2008, p. 10)

Lizarazo’s research on teachers and students in poor schools in urban–rural districts in the state of Mexico (who have had access to some kind of technology) shows the source of difficulty in their appropriation of these technologies. It does not derive from a state of “cybernetic anxiety” at an individual level but from “a sort of collective anxiety in two senses: that of wanting something that you can’t have, and the hopelessness in knowing that you can’t have it” (Lizarazo, 2008, p. 9). According to Lizarazo, this anxiety provokes a double paradox, on the one hand between the imaginary representation of ICTs as an opportunity for social inclusion, and that of real exclusion, “of radical differentiation and anachronism for those who don’t have access to it, or lack the resources or skills to use it” (Lizarazo, 2008, p. 9). On the other hand, an almost irresolvable tension arises between the role that teachers should play as facilitators and providers of socially legitimate knowledge and the students’ computer skills, which surpass the teachers’ own knowledge and understanding. The outcome is not only a disparity in terms of skills, but also a profound questioning of the teacher’s role as the mediator of knowledge and as the authority to regulate what should or should not be learned.

It is almost a state of teaching perplexity when faced with the technological boom, a perception of fragility, anachronism and unequal footing in which teachers see themselves regarding the abilities, faculties and possibilities they find in their students in an increasingly computerized environment. Thus we suggest a series of states: 1. *instability*, because it seems increasingly difficult to sustain their position as the core of the pedagogical process; 2. *urgency of adaptation*, when faced with a technological change that they cannot follow (the students’ computer language scares them, and they are frightened of the circulation of technological devices that they couldn’t even name if they wanted to). But, the issue is that they end up convincing themselves that they will not be able to stabilize themselves or adapt to the new context. (Lizarazo, 2008, p. 9)

In Argentina, the publication *Yo con la computadora no tengo nada que ver* (I Will Have Nothing to Do with the Computer) (Cabello, 2006) argues that projects to incorporate ICTs in schools did not consider either the teachers’ positions or their previous knowledge, which explains to a great extent their resistance to ICT usage

for pedagogical purposes. This research argues that even if educators were open to incorporating computers into their teaching, they would find that the school and the technology are located in different worlds and have different logics; thus, the teachers feel they lack technological skills and knowledge and find their role in guiding the processes of ICT-mediated learning very difficult.

Final Considerations

This chapter has intended to map the patterns of use in Latin America at both the macro and micro levels. We have considered macro sociodemographic and economic variables with respect to ICT inclusion, as well as micro-level concerns, looking at children and youth's appropriation strategies of these technologies and analyzing the changes that have taken place for them as individuals, as well as in the different institutions in which they are inserted, mainly the family and the educational system. Although the lenses differ in both perspectives, there are consistencies when summarizing the main findings: (1) collective access to technologies plays an essential role in disseminating ICTs in the region and generating complex patterns of appropriation; (2) the role of the family is an essential driver for ICT access – both parents and siblings are important factors (the first mainly as purveyors of infrastructure and the second as providers of cultural capital and skills); and (3) ICTs are used in a media and communications ecosystem that includes traditional technologies such as radio, TV, and telephones, and within this ecosystem the main use of ICTs is to communicate with others.

The realities of incorporation and appropriation of ICTs in the region, particularly in the case of adolescents and young adults, are inscribed in family, work, and social conditions in which they operate daily. As Dina Krauskopf (2008) has asserted:

[For young people] stability no longer comes from predetermined sequences, delimited geographical spaces and univocal projects. It no longer has to do with linear, continuous trajectories, but with feelings that are expressed in life strategies and in the use of resources that fan out into alternatives. (p. 168)

The flexibility and mobility of life trajectories has become a common brand of this age, particularly affecting youth patterns in terms of long-term horizons and projects. In some respects, their sophisticated uses of technology, in comparison with older generations, makes them more attractive for the job market. Their participation as subjects of production, where they are both symbolically and materially recognized, is an essential component of the future.

This view reflects on childhood from a sociological perspective (Livingstone, 2006), where the child/adolescent is as much an agent of change as a subject of appropriation of new technologies. In this sense, the Internet and mobile phones

provide the youth a symbolic platform that compensates and substitutes for the lack of power in their real daily lives (Winocur, 2009). Faced with the obstacles of inclusion erected by many traditional institutions – particularly those involved with education, employment, and access to power – the young have developed flexible and mobile strategies of inclusion on the narrow margins of the formal routes available to them.

In a region where the socioeconomic context offers contrasting realities, the digital divide is a concept that still has explanatory potential (Compaine, 2001). Despite the efforts to provide greater connectivity and access, a subject that was approached mainly in the first part of this chapter, inequality is still rampant in the region. However, the real stakes are to be assessed not solely in terms of traditional access variables of infrastructure but, as the second part of this chapter has intended to show, by understanding how the youth of a developing region incorporate these technologies into their daily life strategies. The meaning of these technologies is embedded in their patterns of use.

NOTES

- 1 This is the case for the *Compromiso de San Salvador* (San Salvador Compromise), approved at the second *Conferencia Ministerial sobre la Sociedad de la Información en 2008, el eLAC2010* (2008 Ministerial Conference on the Information Society, eLAC2010). Some of the main goals of this compromise include supporting the development of community-based networks (like computing centers, or *telecentros*); extending high-speed Internet coverage to 70% in urban areas; increasing the number of community ICT centers that provide access to the Internet; developing indicators that take into account advances in the multi-party process of developing national policies on the information society; and the elaboration of comparative studies on the economic and social impact of ICTs on policies and agendas.
- 2 An exemplary case is the *Plan Ceibal*, which from its implementation in 2007 to its completion in 2009 catapulted Uruguay to the top in terms of Internet access.
- 3 <http://www.tnsglobal.com/market-research/technology-research/gti.aspx>
- 4 In 2009, 93% of Latin Americans had access to a cell phone (compared to 30% in 2002), while the world global average is 73% (ITU World Telecommunication/ICT Indicators database, 2010).
- 5 In this investigation the data came from an online questionnaire that was filled out in urban education centers in seven Latin American countries, which excludes all of the schools that do not have Internet access and that are located in rural areas.
- 6 It is worth clarifying that Argentina should be included in the first group, but at the time that OSILAC determined the three groups, the country had not provided data on ICTs. The variables were included in household surveys in the INDEC in 2007.
- 7 The authors point out that while in developed countries 1 to 17 users share one Internet host, in Latin America this number goes up to 134 (Maeso & Hilbert, 2006, p. 10).
- 8 SNCC: *Sistema Nacional de Consumos Culturales*. This program depends on the Media Secretariat of the Presidency.

- 9 Argentina, Brazil, Colombia, Chile, Mexico, Peru, and Venezuela.
- 10 The work of researching and systematizing the qualitative studies was done by Jaime Piracón, a student of the Masters Program in Social Sciences of FLASCO Argentina. We must point out that the trends mentioned correspond to the qualitative studies that were available on the Internet for consultation in the countries cited. In this sense, although they are very significant for the experiences studied, and for others that could develop in similar conditions, they cannot be generalized to the whole region, especially for those countries with a giant digital divide such as Haiti and some Central American countries.
- 11 It is important to note that all of the studies reported research carried out in diverse sociocultural situations where there was some form of incorporation and access to ICTs. Thus, their level of generalization and explanation leaves out areas where the large majority of the population does not have ICT access, as is the case with Haiti (98%).

South Asian Digital Diasporas

Remixing Diasporic Youth Cultures

Radhika Gajjala and Yeon Ju Oh

ABSTRACT

Some present-day rearticulations of South Asian diasporas are identified through the politics of nation-state, while others take shape through more complex transnational linkages. In this chapter, Radhika Gajjala and Yeon Ju Oh focus on diasporas that have formed along transnational affective links based in fandom, popular culture, and music online. For these rearticulated South Asian diasporas, digitally produced and circulated media play a significant role. This chapter examines the techno-mediation of such diasporas through “machinima,” focusing on three examples of South Asian digital diasporic productions: (1) the work of Indusgeeks.com; (2) machinima produced by “desi” players of a computer game, *World of Warcraft* (WoW); and (3) the traveling meme of Daler Mehndi’s “Tunak Tunak Tun” on YouTube. The authors use these examples to show how the circulation and remixing of “Bollywood” media provide nostalgic, affective engagements for diasporic South Asian youth, while at the same time doing important cultural labor for the Indian state and culture industries.

Introduction

Since the early 1990s, a time that coincides with global access to the Internet in the form of the World Wide Web, certain categories of South Asian diaspora have been rearticulated through techno-mediation. Such rearticulations are based in naming of diasporas through the politics of nation-state, while others are based in naming of diasporas through transnational linkages along with the struggle for an autonomous nation-state (as in the case of Tamil Eelam diasporas). Still others are rearticulations along transnational links based in fandom, popular culture, and music online. Digitally produced and circulated media play a significant role in such South Asian diasporas. In the case of the Indian nation-state, “New Bollywood” is significant as both a site where new digital technologies become widely available (Booth, 2008) and a space that invokes nostalgia for an imagined homeland for the non-resident Indian (NRI) population. At the same time, a particular section of the NRI population is being encouraged to “return home” to establish transnational industry and business in India. In turn, the Indian government and industry have mobilized the term “diaspora” to build transnational connections. In this context, the notion of “digital diaspora” has become a way to envision and build networks of transnational capital and labor.

This chapter works from this background and explores how Indian-identified artifacts, practices, soundbytes, and images travel through digital worlds in the form of machinima.¹ We argue that social formations in these virtual spaces reproduce notions of “Indian” through online diasporic networks. These social formations are routed through renewed identifications and re-memberings, as they actively, even intentionally, contribute to processes of transnationalization of labor and business through recoded online and offline subjectivities. These byte-sized representations of Indianness travel and flow through digital circuits, circulating and remixing into formations that rearticulate global identities.

In this chapter we specifically focus on three examples of South Asian digital diasporic productions: (1) the work of Indusgeeks.com; (2) machinima produced by “desi” players of a computer game, *World of Warcraft* (WoW); and (3) the traveling meme of Daler Mehndi’s “Tunak Tunak Tun” on YouTube. Indusgeeks is an organization formed through the entrepreneurial drive of its Indian founders. The group began as a productive engagement with play and work in the online world of *Second Life* and is now a full-fledged business, offering “metamersive” services.² Most of the geeks who are operating the website are Indian-identified and located in the United States. In contrast, Daler Mehndi is an India-born bhangra/pop singer (the “King of Pop” according to the promotional website <http://www.dalermehndi.com/>), who was trained in traditional Punjabi music but who rose to become a transnational popular music icon outside of Bollywood (although eventually doing work for Bollywood as well).

The first part of this chapter lays out the theoretical background, focusing on studies that examine the interplay of nostalgia and national politics, as well as how

members of South Asian diasporas work and play within a global economy. While members of such diasporas are granted citizenship and a sense of belongingness by the Indian nation-state, they are mobilized to perform transnational forms of cultural labor in return. Research on the era of “Bollywoodization” or “New Bollywood” helps us look at the dialectic relationship between diasporas and their associated nation-states. In the second part of the chapter, we discuss examples from popular culture and digital worlds to show how South Asian diasporas are manifested both as Indian and transnational diasporas simultaneously.

Part I: Theorizing South Asian Diaspora

Writings about postcolonial diasporas and imagined communities are filled with discussions of nostalgic connections to the homeland. Of course, postcolonial, feminist, and other critical theories of diasporas and transnational travel have challenged the logic that locates diasporic emotional yearnings in a simple nostalgia for a past homeland. For instance, Jigna Desai (2003) has pointed out that formulations that see nostalgia as the defining diasporic emotion – a yearning for a past manifested as a “homeland” – ignore the economic and political power relations and implications of diasporas (p. 1). Further, it is clear from past work on South Asian diasporic identities that the politics of transnational mobility in any moment in history requires members of the diaspora to rearticulate their identities in relation to the contemporary political moment in racial politics. This process of diasporic identity formation manifests, fundamentally, in continuous negotiations over one’s sense of place and belonging.

Avtar Brah’s (1996) writing on the meaning of “home” demonstrates this complex process of negotiation. She identifies two different meanings of the referent “home” in questions posed to her during an interview for an admission to a US institution of higher education by an all-male panel of interviewers. In one of the questions asked of her, she writes, “home” implied

a site of everyday lived experience. It is a discourse of locality, the place where feelings of rootedness ensue from the mundane and the unexpected of daily practice. Home here connotes our networks of family, kin, friends, colleagues and various other “significant others.” It signifies the social and psychic geography of space that is experienced in terms of a neighborhood or a hometown. That is, a community “imagined” in most part through daily encounter. This “home” is a place with which we remain intimate even in moments of alienation from it. It is a sense of “feeling at home.” (Brah, 1996, p. 4)

In a separate question, Brah explains, home referred to “an invocation of narratives of *the nation*” in which one’s identity is rooted (p. 3). For Brah, who is a Ugandan of Indian descent, home is plural rather than singular – simultaneously interwoven as

both India and Uganda. However, in racialized or nationalist discourses one's home is confined within a place where races and ethnicities can be traced back by others. Members of South Asian diasporas across the globe are not necessarily members "of" a certain nation-state, although they live "in" those places and identify partly as belonging to those nations. Their looks and accents become signifiers that determine their identities in racially and ethnically stratified societies.

In recent decades there has been a shift in how transnational business and media networks take shape and operate, which highlights the fact that diasporas are not (and have never been) pulled together merely by a nostalgic association with one single "homeland." The articulations of nostalgia for such a "return" to a homeland miss the productive and re-membling nature of how nostalgia and the politics of affect play into emerging futures of diasporas. Here we purposely spell it as "re-membling" in order to highlight both the psychic acts of remembrance through individual and group memory and the social relations produced through the assertion of commonality so as to increase the membership of such groups. This implies, then, that the re-membling of such diasporic communities happens through choice, selection, and recruitment, signaling active inclusions and exclusions in social relations, based on the politics of what counts as correct emotion and nostalgia. Particularly, we focus on the emerging futures of diasporas that travel transnationally, carrying packaged and byte-sized "homes" along with them, as members rearticulate their sense of self by placing themselves, and in turn being placed, as South Asians or Indians in diaspora. Avtar Brah asks, "what is the relationship between *affect*, *psychic modalities*, *social relations*, and *politics*?" (1996, p. 5). In this chapter we examine such relationships in Indian digital diasporas.

In an interrogation of English-language Indian films of the 1990s, such as *Hyderabad Blues* (Kukunoor, 1998) and *Bombay Boys* (Gustad, 1998), Jigna Desai challenged, as too limiting, the idea that "diasporas are 'hailed by' the narratives of the homeland nation-state that activate sentiments of nostalgia and belonging" (2003, p. 45). Pointing to the strong impact that South Asian diasporic populations have had on South Asian nation-states, she writes that "focusing only on the homeland nation as origin of culture, tradition, and values and the state as authority and granter of citizenship can overshadow an examination of the economic and political power in relations between diasporic communities and nation-states" (p. 45).

In her unpacking of how diaspora and the nation-state function dialectically to produce a transnational South Asian politics, Desai does not discount the use and function of emotion and affect in diasporic yearnings for return. But she adds an important dimension to this theorization of diaspora – namely, that the relationship between diasporic populations and the nation-state, and the articulation of nostalgia for a homeland, are shaped through the economics and politics of transnational capital and labor flows. She explains "that while diasporas hail the homeland through nostalgia and return, they do so when convenient. The homeland nation's heralding of diaspora has little to do with the everyday lives and interests of the non-elite classes who are clearly critical of and ambivalent in regard to diaspora" (p. 55).

While we cannot totally discount the role that nostalgia plays in how the home-nation can mobilize, shape, and invoke the involvement of those in diaspora, we need to observe how diasporic desire for home functions for those who identify as members of diasporas, and for national and transnational politics. These forces sometimes mutually reinforce each other and are sometimes at odds with each other, in the production and reproduction of tradition and culture in various contexts. It is critical to understand how mediated nostalgic storytelling comes into play in these reproductions. As previous literature on online South Asian diasporas shows, the “hailing” based in caste-based and religion-based forms of nostalgia in fact has produced certain kinds of community that have exerted some political influence in the “homeland” (Bahri, 2001; Rai, 1995).

Today, Indian-identified offline bodies are building socially networked Indian diasporas online through a similar placement of affect and cultural labor. Technologically mediated diasporas take shape at online–offline intersections. Community formations that emerge through wired and networked portable digital devices help counter the sense of isolation and alienation faced by today’s youth as they continually uproot and re-place locations in their mobile work and play lifestyles. In such mobile portable communities, affective links, sometimes manifested as “nostalgia,” are produced through re-membered pasts that are rearticulated through such groups forming and living partly online, in virtual communities.

Divya Tolia-Kelly (2004) writes about “locating processes of identity” through an examination of how everyday artifacts and

[i]ndividual objects relate to individual biographies, but are simultaneously significant in stories of identity on national scales of citizenship, and the intimate domestic scene left behind. The new site of home becomes the site of historical identification, and the materials of the domestic sphere are the points of signification of enfranchisement with landscapes of belonging, tradition and self-identity. (p. 315)

Such signification of enfranchisement with landscapes of belonging is produced through a process of reconfiguring memory and affective engagements. Transnational environments that are made accessible by online media and mobile technology create media landscapes where scattered fragments of nostalgic memory and affect are produced and distributed. Meanwhile, diasporic individuals who form groups and communities of mediated exchange and sharing, and who live in these environments, shape the globalized world. In other words, ethnoscaping is formed when people move across national boundaries not only in physical ways, but also in more virtual or mediated ways, as occurs in call centers or virtual communities. Despite the existence of material beings dispersed over the world, they are geographically, socially, and culturally located in their “home” through specific practices of memory and affect that serve as forms of racial and ethnic authentication.

Particular South Asian cultural commonalities have also emerged through mass media and communication technologies since the early 1960s, creating new

communicative spaces of diaspora. The recognition of these culturally representative images, texts, and sounds serves as a “remediation” of an imagined community. Rituals of authentication emerge through expectations of recognition of these commonalities present in reproduced and remixed digitally mediated images, texts, and sounds. Reproduction and remixing occur through a post-1990s “Bollywoodization” of South Asian-centric digital environments (Rajadhyaksha, 2002). These cultural formations are increasingly “Indianized” in a continuing synergy with satellite TV (the South Asian package) (Punathambekar, 2005). Here, themes such as “Yeh Mera India” (this is my India) are reiterated through a continuum of commercialization, Bollywood films, music, TV serials, global TV format-based productions such as *Indian Idol*, as well as advertisements for New York Life Insurance. Communities of online and offline bodies form around digitally mediated communicative practices, often centered around the sharing of Bollywoodized media. These communities build pockets and enclaves of networked affect. The emergence of seemingly disconnected yet representative cultural symbols in these spaces functions to rearticulate emotional histories through re-placement of affect in transitional place. These online networks transform from contact zones where people from diverse backgrounds encounter one another. These virtual spaces become transitional zones, where people build virtual commonalities and practices, as they place themselves and enhance their skills in global work and play environments.

Our observations are based on years of ethnography in online worlds and social networks, as well as on more than a decade’s worth of ethnographies offline of teens in the United States and in India, playing computer games and using digital technologies. Many of the texts we examine are from the virtual world called *Second Life*, which first became publicly available in 2003 (see <http://www.secondlife.com>). Simultaneously, and a few years prior to encountering *Second Life*, one of us was using text-based MOOs³ in pedagogic settings and also doing ethnography in the online network known as Livejournal. In retrospect, it seems that Livejournal was a precursor to social networking sites that emerged in 2004.

In the recent past, transnational traveling and diasporic South Asians have placed and transmitted affect both audiovisually and sensually through radio, cinema, television, cassettes, video, and letters (and continue to do so). These traveling signifiers combine with physical objects, such as artifacts for living rooms, spices for “authentic” home food, fabric and incense, carried along in suitcases and scattered memories to allow the South Asian diasporic to feel “at home” in various nooks and crannies of the globe. In the age of social media, this packaging has come online in the form of hybrid “desi” popular cultures that leave behind spatio-temporally layered stains and traces of material artifacts in digital space. These are virtual objects that have been placed there by South Asians and those linked to South Asian culture and experience. Such artifacts acquire multiple meanings through symbols and associations as they journey through various networks. The use of remixed Bollywood tunes and ethnic avatars marks South Asian digital diasporic place in virtual worlds such as *Second Life* and *Sims 2*. Facebook and iPhone apps also code nostalgia and

affect through circulating image and sound. Zynga, the makers of *Farmville*, reputedly the most widely played Facebook game online in 2009, was compelled by Facebook-based activism (the campaigning of Indian-identified *Farmville* players through a Facebook group, for instance) to include the Indian flag as one of the artifacts/objects to use in building personal profiles. It also recently launched visual artifacts such as auto-rickshaws, monkeys, and elephants to signal the opening of a branch of its company in India.

South Asian identities are now produced in part within sociocultural digital places constructed by computer software and hardware. Sociocultural and technically produced time-space compression enables members of Indian diasporas to be globally networked and to co-produce their identities. The sociocultural literacies of these inhabitants determine the kinds of free labor (Terranova, 2000) they contribute toward the building of these spaces. The continued inhabiting of these spaces leads to a reorganization of social space and everyday practice, similar to that experience by call center workers from India who are tuned in to time zones and cultural practices in the Western world (Mitra, 2008). They experience a social, affective transformation that orients them toward life in global multicultural communities similar to those encountered in diaspora.

South Asian Digital Diasporas

In this chapter, we extend existing work that examines how technologically mediated diasporas occur at online–offline intersections specifically in relation to the “South Asian,” “digital,” and “diasporic.” Past research on South Asian presence in online spaces has made observations based on studies of online bulletin boards (Rai, 1995), email lists (Bahri, 2001), and websites (Chopra 2006; Mallapragada, 2006). In order to better understand the interplay of globalization and technology, we propose examining how sociocultural formations of youth cultures form online through work and play activities.

There are very specific circumstances that allow us to think in terms of “digital diasporas” – namely, globalized markets as well as the interactive nature of online technologies. At the same time, it is also important to take into account the layered and nuanced ways in which such diasporic subjectivities are produced, if we are to understand how the global/local continuum plays out in specific situations in present cultures and economies. What is unique about the digital time-space continuum is its tendency to record practices and leave behind histories and actual archives, providing valuable data with which to study the use of digital technologies. Significantly, the various texts or representations that are produced in these contexts can be viewed as diasporic in and of themselves. In the formation of these online representations (whether they be written texts, moving images, static images, or three-dimensional representations), there is a certain situatedness, a sense of “landing” somewhere. At the same time, there is an affective reproduction of travel, as well as a sense of

disorientation through encounters with other cultures that simulates a form of culture shock. The unique qualities of these digital contexts and experiences necessitate the use of phrases like “digital diaspora” and “virtual community.”

We use the term “digital diaspora” to talk about how diasporic populations the world over use the Internet to connect to one another. Digital media used for digital diasporic formations are networked and interactive, potentially allowing people from different parts of the world to feel located in one “place.” They provide sites where people with similar interests and similar missions can gather in a common space. Online networks formed through digitally mediated communicative media – whether accessed via desk-top computers, Xboxes, or iPhones – permit the local to exist within the global and vice versa.

The transition from print media to mass media allowed the imagining of common places, or what Anderson (1983) referred to as the convergence of capitalism and print technology. The fatal diversity of human language created the possibility of a new form of imagined community, which in its basic morphology set the stage for the modern nation. As print media were made accessible – actually or potentially – to “the masses,” the world experienced the growth of modern capitalism, as well as the emergence of modern nations and internationalism.

Interactive online technologies help reproduce and enhance transnationalism based on global flows of capital and labor. The interactivity of online technologies in their current forms is a logical extension for global financial networks in particular. The architects of digital capitalism have pursued one major objective: to develop an economy-wide network that can support an ever-growing range of intra-corporate and inter-corporate business processes (Schiller, 2000). At the same time, the combined logic of digital transnationalism with globalized markets and interactive online technologies allows the emergence of digital diasporas.

Bollywoodization of South Asian Digital Diasporas

In mapping affective South Asian/Indian social networks online, we suggest that memory, nostalgia, and affect simultaneously work to place and locate South Asian/Indian identifiers in digital space. In doing so we focus on the circulation and proliferation of “Bollywood” media (whether as clips of music, video, image icons, or *Second Life* and *Sims* avatars), as well as on specific symbols and artifacts that register as “Indian.” Many of these signifiers work in sync with a post-1990s opening of the Indian markets to transnational labor and trade, as they reconfigure and “remix” older images and sounds for the techno-mediated “desi” global workforces. These workers increasingly live in digital diasporic spaces and global–local offline hubs, such as dance clubs and coffeehouses, as well as in multinational corporate environments where they work and play. These groups of young men and women live in remixed and cross-routed communicative spaces of diaspora, carrying partial nostalgic attachments from previous generations as they employ a medley of soundbytes, icons, and

visual loops to produce meaning and community identifications in nodal points. The role of Bollywood-based music is especially important in these online and offline settings, as it provides a link through the scattered visual signifiers. Bodies and avatars sway in motion to sound clips coded digitally through online portals, offline loudspeakers, or iPods and smartphones.

This remixing of South Asian/Indian media artifacts was made possible by structural changes in the Indian film industry. Nilanjana Bhattacharjya (2009) notes the shift in how Bollywood films are now funded since the economic liberalization of the Indian economy in the 1990s. She describes how the Indian government's encouragement of privatization and international investment led to the Indian film industry being increasingly funded through contributions by non-resident Indian investors. This in turn led to a shift in the orientation of the films produced. More and more films were produced for South Asian diasporic audiences. Ashish Rajadhyaksha (2002) refers to this process as the "Bollywoodization" of Indian cinema. Gregory Booth (2008) refers to this period as "New Bollywood," noting the shift in the production technologies and processes for film and music in the Indian media industry to privilege digital formats. "When younger, more technically sophisticated filmmakers and technicians finally introduced digital sound and filmmaking techniques and computers became widely available, a new era began that I call 'New Bollywood'" (Booth, 2008, p. 85). It is this transition in Indian film – whether we call it a "Bollywoodization" or a transition to the "New Bollywood" – that allows the byte-sized packaging of images and sounds from the Indian film industry into South Asian digital diasporic spaces.

Part II: Desi Youth Hanging Out in Digital Diaspora

In the remainder of this chapter, we examine three examples of digital environments built around nostalgic notions of an imagined homeland on the part of people who labor in these environments. These examples show how the practices of identification and engagement within South Asian digital diasporas feed into building a brand of "Indianness" (Bolin & Ståhlberg, 2010) that is inextricably tied to the "Bollywoodization" of Indian and South Asian culture and identity. Many of the transnational venues in these digital diasporas are inhabited by technologically savvy young men and women, with their casual dress codes and urban sensibilities. Some of these spaces are less US-centric than the previous Internet-based South Asian generations. These social network systems and blogs, masked in semi-anonymity, often interrupt offline social conventions. They complicate notions of transnational identity and sexuality, as digital diasporas hide behind Bollywood, manga, and other pop icons and game-based avatars. There is a continuous play on identity and gender, as the Bollywood icons produced in these communities blur the boundary between queer pleasure and the idolization of heteronormative Bollywood themes and stars.

Meanwhile, such communities produce uncertainty about geographic location, as members of these digital diasporas appear to multitask between work, leisure, and offline/online formations of friends.

For this generation, being online is no more unusual than being on the phone as they incessantly text-message, tweet, and “FB” at every mundane moment and download and exchange ring tones, pix, and flix. This group of young South Asians living in digital diasporas is multiply literate and socioculturally flexible and mobile, “hanging out” in online communities of open source developers and various kinds of fan groups. The young people participating in the Indian digital diaspora are producing new layerings of hierarchies and skills. Even as most seem to be just “hanging out” online, many of these young people are reskilling themselves quite desperately in an attempt to outsmart the job market. Of course, there are other participants from more materially privileged backgrounds who are indeed “hanging out” for leisure. Despite this internal hierarchy, the everyday practices of mobile generations in digital diasporas involve and invoke new and different kinds of problem-solving spaces from those inhabited by the materially underprivileged of the world.

Sunaina Maira (2000) has traced the origins of diasporic youth subcultures in locations offline. In her article on “Henna and Hip Hop,” she writes

The youth subculture created by South Asian American youth in New York City is based on remix music that was first created by British-born Asian youth in the 1980s and that layers the beats of bhangra. [. . .] It mixes a particular reconstruction of South Asian music with American youth popular culture, allowing ideologies of cultural nostalgia to be expressed through the rituals of clubbing and dance music. (p. 334)

For Indian diasporic youth, as Maira describes, their collective memories of the homeland in which they have never lived are re-membered through Bollywoodized cultural forms such as music and dance. Social spaces like the youth clubs function to produce “the ideologies of ethnicity, pan-ethnicity, and nationalism,” as diasporic youth practice cultural rituals they believe to be “authentic,” thereby placing themselves within the imagined Indian community (p. 334). The emergence of computer-mediated social networks has brought a spatial shift from metropolitan-centered to online spaces for diasporic youth culture.

In the virtual world of *Second Life*, several such dance clubs exist where young men and women of South Asian descent and their non-South Asian friends “hang out.” At least that is how it appears to the *Second Life* players who visit these clubs. Here we base our observations on our experience visiting these clubs mostly in 2007, 2008, and 2009. Our understanding comes from a form of participant observation, or “deep hanging out,” in various dance clubs on *Second Life*, in order to understand some sociotechnically scripted codes for behavior in such environments. We visited dance clubs that self-describe as Hispanic clubs, Middle Eastern, Reggae, Jazz, “desi,” and Bollywood-focused. In *Second Life*, no “place” stays static for long. Groups and

individuals are continually rebuilding and relocating; therefore, observations of these dance clubs can only be located in specific affective experiences and memories of the events, and on snapshots and various YouTube videos taken by *Second Life* residents as they visit these clubs.⁴ Of course, merely viewing the videos or images does not provide a sense of how it actually feels when immersed in the environment. Thus as researchers we rely on our own readings of performative cues to describe and examine these activities.

All these virtual dance clubs have basic scripted objects – a dancing ball, or a floor with dance script – to animate the avatars.⁵ They also use streaming media, where the songs are streamed from a server (such as Shoutcast or Icecast) onto the *Second Life* location. Most of them have tip balls or some form of money-collecting scripted objects, and some also have exploding objects that are scripted to allow visitors to enter into a competition for a cash prize. Some clubs have themed dances and competitions for dancers (this is also done through scripted objects), where fellow dancers get to vote for the “best dressed female in pink” or other themes decided by the club owners.

In dance clubs focused on Indian themes, there is often a stock set of Bollywood remix music (and sometimes even video) streaming in. The *Second Life* avatars in these clubs are dressed in a variety of clothes, but more and more of them (since 2007) are dressing in ethnic-seeming garb, mostly modeled after Bollywood characters’ dresses.

As far as the dance clubs with Bollywood music are concerned, Indianness is established mainly through familiarity with the music being played and a basic minimum knowledge of Hindi, which is demonstrated in conversation amongst avatars in the club as they dance on. “Where are you from?” seems to be a question often asked of newcomers in an attempt to connect to South Asian origin stories. Bollywood is invoked as representative of India in such mediated environments but also serves as an apolitical and safe common language.

A narrow interpretation of these social spaces as produced through a purely nostalgic longing for an imagined homeland leaves the national politics of the Indian government and the implications of transnationalization unexamined. The interplay of technologies and cultural artifacts connects Indian diasporas over the world, in particular those who have economic power, and attracts them to invest in the homeland. In this sense, Bollywood not only serves up nostalgic pleasure, it also incorporates specific and selective ideologies and resonances from Indian diasporic communities into the building of a “Global India.” Those who produce Indian cultural artifacts online perform important cultural labor to produce the nation’s brand in the global marketplace. This is well demonstrated in a machinima produced by Indusgeeks.

In 2007, Indusgeeks produced a machinima called “India in *Second Life* – shot on a location on Bollywood Island.”⁶ “A new world beckons” is the first line that appears on the screen, while young men and women from all vocations are shown rising up in a trance and running toward what turns out to be “Bollywood Island” in *Second*

Life. The avatars, mostly wearing Bollywood-style Indian dresses, gather hand in hand to salute the Indian flag, as the video concludes with an invitation to viewers to “Join us . . . in Second Life.”

The notion of a new world, and the seemingly open, inclusive invitation to participate in that world, resonates with the discourse of “Bollystan,” or “India’s diasporic diplomacy” (Khanna, 2005). Parag Khanna (2005) describes Bollystan as “a diasporic salad bowl of ethno-commerce and a new model of geographically transcendent sovereignty” (p. 17). Bollywood stars like Aishwarya Rai and Sharukh Khan have been proclaimed Indian ambassadors. In this mediated environment, Bollywood increasingly becomes representative of “India” for much of the second and later generations of diasporic Indians. As Ashis Nandy (1998) has pointed out, Bollywood provides categories of meaning making for a large population of Indians the world over. That is, Bollywood provides common language for diasporic Indians across generations whatever their actual geographic locations are.

From the development of state councils and academic centers on the diaspora to the prevalence of NRI characters in Bollywood cinema, the nation-state advances its interest in diasporas in different modalities, articulating its varying relationships with diaspora based on contradictory and complementary interests. Since the structural adjustment policies of the 1980s and 1990s requiring India to “liberalise” its economy by devaluing its currency, opening its markets to transnational and foreign corporations, and increasing its debt, the ideal diaspora is one that willingly exchanges economic and technological investments for national membership and state citizenship. (Desai, 2003 p. 2)

The characterization of a Bollywoodized, 3D “new world,” evident in the Indusgeeks machinima described above, serves to reinstate existing offline hierarchies and binaries. It does this while also reproducing a very specific, euphoric vision of the future that brings together India’s vision for development through the IT sector with its entertainment industry’s call to specific groups of NRIs to return as investors.

Two-dimensional web space does not always offer the flexibility or excitement of three-dimensional platforms like *Second Life* in helping diasporic youth perform their cultural and national identities. Within such three-dimensional environments, youth seek venues where their cultural identities can be articulated in digital cultural artifacts. In addition to machinima produced from *Second Life* gameplay, another site of South Asian digital diasporic engagement is in remixed videos and machinima found on YouTube made through the platform of the computer game known as *World of Warcraft* (WoW).

These videos and machinima not only illustrate how South Asians code affect within computer game worlds as they play through the use of Bollywood music, they also show glimpses of the struggle over racial identity within a non-customizable online world like WoW. Here the categories and game routines are coded so that players do not have much flexibility regarding the appearance or clothing of the avatar. This is unlike malleable games such as *Sims 2*, where users can, within limits, produce custom meshes for avatar appearance and clothing. One video demonstrat-

ing such limitations was posted to YouTube in November 2006.⁷ The video uses figures from the visually dwarf-like “Mage” race from *WoW* to depict a Bollywood aesthetic in machinima form.⁸ In the comments section on YouTube, some viewers critiqued the producer of the machinima for using a figure that does not fit Bollywood appearances. One user stated, “Very good but the gnomes are not so good for this song.”⁹ Another wrote, “Good vid, but it’d be better if you used Dranei models instead. They are THE Bollywood race imo. :)” The machinima creator noted, in response, that “This vid was made before addon, so only_ oldschool models.” And indeed in a later video uploaded by another user in June 2007, a Dranei female avatar is used as a central character. The machinima, named “wow dranei dance,”¹⁰ depicts a very sexualized rendering of a Dranei female avatar dancing to the tune of Asha Bhonsle and Kronos Quartet performing “Koi Aaya Aane Bhi De.”

The remixing of a Hindi song within *WoW*’s environment demonstrates Indian diasporic youth’s struggles to inscribe their identities through cultural artifacts online. In this example, cultural identities are imagined and re-membered by Bollywood’s representation of Indianness, thereby assuring the role of Bollywood in constructing the image/brand of “Global India.” In performing such a branding role, Bollywood mobilizes transnational labor, in particular those who play with cultural artifacts and digital technologies that serve to form a networked, imagined Indian community across the globe.

In June 2007, another YouTube user posted a *WoW* machinima video that also used an avatar from the Dranei race and featured a hooded male character dancing to the Hindi popular song “Tunak Tunak Tun” by the widely known Punjabi popular music singer and performer, Daler Mehndi.¹¹ The background song to this video was first performed by Mehndi in 1998.¹² The song became an Internet meme because of its random silliness, as the Wikipedia entry about the song notes (Tunak Tunak Tun, n.d.). Judging by the many videos produced transnationally that referenced the Daler Mehndi song, this meme caught on across contexts and traveled through digital networks.¹³ Significantly, Daler was neither a Bollywood singing star (even though he did a few songs for Hindi films) nor an NRI at the time this Internet meme originated.¹⁴ Nevertheless, he was criticized by some in the Bollywood industry, who suggested his popularity was due more to the young girls dancing on stage with him than to his own talent and music.¹⁵ Subsequently, however, he has worked with Hindi Films, such as in *Rang de Basanti* released 2006, for which he sang the title song under the musical direction of A. R. Rehman. Thus Daler’s affective labor, constantly referenced in online social spaces, has become a part of the Bollywood industry’s attempt to evoke a sense of community in digital diasporas.

Diasporic Youth Culture as Transnational Conjuncture

Each of the examples of South Asian digital diasporic engagement discussed in this chapter follows different trajectories of labor, online cultures, and global circulation.

For the moment at least, each one has become transnationalized by routing through Indian-based locations of origin and circulation (one from “Virtual India” in *Second Life*, the second from the computer game *World of Warcraft*, and the third from offline Punjab). They now inhabit global spaces of transnational capital. The machinima by Indusgeeks produces an idealized vision of India in sync with the utopian discourse around the notion of a “second life,” performing the dual function of selling both *Second Life* and a particular vision of India and its future. The Indusgeeks *Second Life* video is clearly connecting to a nation-state and a particular vision of development for the nation-state. The examples from the machinima produced using WoW demonstrate racial identifications of a Bollywoodized form of Indian identity, as well as the affective pull that Bollywood music has for producers and viewers. These machinima locate a diasporic *place* at the intersection of the fantasy world of WoW and the fantasy world of Bollywood – in this case there is likewise an affective pull, layered and remixed. Finally, in the Internet meme around Daler Mehndi’s song, we see that the identifications travel through transnational contexts with people from a variety of backgrounds (including youth from US college classrooms as well as fans of Anime and Manga worldwide¹⁶). While Daler Mehndi was not closely associated with Bollywood at the time he produced the “Tunak Tunak Tun” video, it is significant that in later years he worked for major Bollywood hits such as *Rang de Basanti*, thereby serving in his own way as an ambassador of Bollystan – the “new model of geographically transcendent sovereignty” for India.

What sorts of convergences, conjunctures, and connections emerge in relation to globalization and migrant populations the world over along with the emergence of new forms of digital networked media? How are transnational diasporas manifested in relation to new technologies and to evolving forms of economic and cultural globalization? These are questions that have underpinned this chapter, which has mapped a particular route through digital space to explore how new conjunctures and convergences are produced in Indian digital diasporas.

NOTES

- 1 Machinima is the use of real-time 3D computer graphics rendering engines to create a cinematic production. Most often, videogames are used to generate the computer animation. Machinima-based artists, sometimes called machinimists or machinimators, are often fan laborers by virtue of their reuse of copyrighted materials. The practice of using graphics engines from videogames arose from the animated software introductions of the 1980s demoscene, Disney Interactive Studios’ 1992 videogame *Stunt Island*, and 1990s recordings of gameplay in first-person shooter (FPS) videogames, such as id Software’s *Doom* and *Quake*. Originally, these recordings documented speedruns – attempts to complete a level as quickly as possible – and multi-player matches. The addition of storylines to these films created “Quake movies.” The more general term machinima, a misspelled portmanteau of machine cinema, arose when the concept spread beyond the Quake series to other games and software. After this generalization,

Even more intriguing, an object's behavior could be based on something outside the game: virtual weather in an area could be based on real-world weather reports, for example, or a soccer ball could move based on telemetry from a real-world soccer ball."

Fear and Hope

The Politics of Childhood and Mobile Media

Damien Spry

ABSTRACT

Mobile media are increasingly ubiquitous in the lives of children and young people worldwide. In this chapter, Damien Spry uses case studies from Japan and Australia to examine moral panics and regulatory responses to children's use of mobile media. Emphasizing the politicization of young people's mobile media use, he argues that "childhood" and "new media" are discursive sites where the hopes and fears about future generations are powerfully expressed and negotiated. While there is a great deal of public discourse about children and mobile media, Spry notes the relative absence of young people's voices from this discourse, and questions how their voices might be more audible in the debates that affect them.

This chapter addresses the politics of childhood, youth, and mobile media, providing an overview of some of the issues found in research, public discourse, and policy discussions and then focusing on the national contexts of Australia and Japan.¹ I examine political discourse relating to the use of mobile media by children and young people, and public policy that regulates and/or promotes their mobile media use, considering the ways that particular sociocultural constructions of childhood and youth are deployed and reproduced. I seek to make explicit the ways that children

The International Encyclopedia of Media Studies, First Edition.

and young people are discursively constructed in public debates about mobile media use, and how these conceptions are translated in public discourse and policy. I also call attention to the relative marginalization of children's voices in the political discourses about them and their capacities as mobile media users, and I consider the potential for children and young people to participate in, subvert, or render insignificant, these political and policy interventions.

In the second half of this chapter, I discuss a number of cases from Japan and Australia where significant public debate emerged on children's mobile media use. The national contexts of Japan and Australia are instructive; they represent two relatively wealthy and technologically advanced societies with explicit public agendas regarding connectivity and access, yet with very different cultural heritages and significant differences in the demographics of their respective populations. The cases I discuss bring into sharp relief some commonalities in the politics of youth mobile media in these different contexts. However, these examples also raise questions about how the politics of mobile media may be grounded by national and local cultures. Ideas about childhood certainly do vary greatly across cultures (and have varied historically). Use of mobile media also varies. The faster areas of growth in mobile media use are in what are sometimes referred to as "developing" or "emergent" markets, including much of Africa and parts of Asia-Pacific, especially China and India (International Telecommunications Union, 2010). There is an emerging body of work on mobile phones as tools for development (e.g., Jagen & Heeks, 2008; Waverman, Meschi, & Fuss, 2005), in post-conflict countries (e.g., Best, Smyth, Etherton, & Wornyo, 2010), and by migrant workers (e.g., Panagokoras & Horst, 2006). Yet the studies of children and young people as mobile media users have hitherto been restricted largely to examples from Europe, North America, and the wealthier countries of the Pacific Rim. There is a critical need for more research, and for more interaction between research and policymaking. But with this in mind, it is important to note that the argument offered here has an essential caveat: while the approach I have taken may be applied globally (with some variation), we cannot assume that the conclusions would be identical in every regional, national, or local context.

As recent studies have demonstrated (Matsuda, 2010; NSW Commission for Children and Young People, 2009; Spry, 2010), it has become unremarkable for Japanese and Australian elementary schoolchildren to possess mobile phones. Nowadays, between 60% and 85% of 11- to 16-year-old children have a mobile phone, and the average age at which children first gain possession of a mobile phone is getting younger. In the early years of the commercialization of the mobile phone, this would have been unthinkable: mobile phones were largely reserved for taxi companies, police and emergency services, and entrepreneurial elites. Then, the "bricks" that the Gordon Geckos of Wall Street held in such high regard were too large, too heavy, and too expensive for children; even if they were not, mobile phones were considered unnecessary. It was not until technological improvements leading to smaller and cheaper handsets, and realization among telecommunications

companies that a profitable younger market existed, that the age of mobile phone users dropped significantly. Young mobile users enjoyed the increased capacity for peer communication, and creatively turned the mobile phone into a device for new, youth-focused forms of expression and sociality. That, coupled with the increasing demands of work, commuting, and schooling which made families begin to find it difficult to stay in proximate contact with each other, led the mobile phone to become an important tool for managing relations within families and peer groups. Having a mobile phone, for many current elementary school students,² has swiftly moved from the unthinkable to the unremarkable; it is now bordering on the essential (Matsuda, 2009, 2010).

Nevertheless, concerns that have been associated with youth mobile media use since the 1990s persist in popular and political discourses. Such concerns include: the way mobile phones now function as markers of social status and the growing necessity of mobile phones for social inclusion among youth and children; the intrusion of mobile phones into school life and education; and the association of mobile phone possession, display, and use with aspects of adulthood, such as participation in the economy and in the adult worlds of love, sex, and violence. Meanwhile, the evident popularity and ubiquity of mobile phone use by children and young people have left adults (including policymakers) with a burning question: how to take advantage of the possibilities of mobile media while managing their uses so as to minimize harm to young people? Another important question is less commonly posed: how can we include children and young people in policy discussions that relate to them? The growing body of research on children, youth, and mobile media can help adults understand young people's experiences, at the same time informing policy discussions aimed at promoting socially beneficial uses while discouraging more problematic behaviors associated with mobile media use. Unfortunately, the extent to which public policy has been informed by the research thus far appears minimal, as archetypal attitudes about children and media use predominate.

Research on Children and Young People's Mobile Phone Use

In the early days of mobile media studies, the idea of preadolescent children as mobile media users was of marginal interest. As young people began to take up the mobile phone in greater numbers – first teenagers in the late 1990s, and then elementary school-age children in the 2000s – researchers began to take interest. Youth mobile media use began to be associated with new cultural forms of expression. In an early example, texting via short message service (SMS) became an issue, as specific linguistic practices were identified and analyzed. The increasing use of mobile phones by children also raised other areas of concern. The fear of physical harm due to exposure to electromagnetic radiation, the risk of inexperienced users

accumulating large telephone bills, and anxieties about addiction or other antisocial behavior were added to unease about the impact of new communicative forms (such as SMS) on traditional standards of literacy. Initially, there was considerably less enthusiasm about the possibilities for mobile media as an educational device than there was concern about its potential for disruption and even danger. Other studies looked at the important role mobile communication had in facilitating, and transforming, youth sociality. Later studies, from the mid-2000s, included the social and political relations within families as an important aspect of youth mobile media use.

All these aspects of mobile media use by children and young people have become important themes in the field of youth mobile media studies. Rich Ling (1999a, 1999b, 2000a, 2000b, 2000c; Ling & Helmersen, 2000) introduced many of these themes in the early years of the 2000s. Since then, the field of mobile media studies has grown steadily. The first significant edited collection on mobile media studies appeared in 2002 (Brown, Green, & Harper, 2002). Since 2005, the published literature on mobile media studies has grown at a greater pace (see Castells, Fernández-Ardèvol, Qiu, & Sey, 2007; Goggin, 2006; Harper, Palen, & Taylor, 2005; Ito, Okabe, & Matsuda, 2005; Katz, 2008; Ling, 2005, 2008). Recently, a number of notable publications emphasized mobile cultures in the Asia-Pacific region, including the countries covered in this analysis: Australia and Japan (see Goggin, 2008; Goggin & Hjorth, 2009; Hemelryk, Dindorfer Anderson, & Spry, 2010; Hjorth, 2009). Books and publications on mobile media that appeared during this period included studies that examined their uses by children and young people.

Relevant scholarly research to date can be categorized according to a series of themes, three of which are well established: (1) youth sociality, culture, and identity;³ (2) moral panics, risks, and responses;⁴ and (3) mobile childhood, parenthood, and families.⁵ An additional, less established theme concerns the use of mobile media in formal educational environments, for pedagogical purposes. This theme, commonly referred to as “mobile learning,” is likely to gain ground if (or when) mobile media are more fully incorporated into school classrooms. A fifth theme might be called “the future of mobile media use,” and includes research that employs terms like “ubiquity” and “convergence” to describe the changing media environment. This work, often associated with discourses of “digital natives,” or “the net generation,” seeks to identify new forms of media use and new types of users.

Common characterizations of mobile-mediated childhood found in both the literature and in public debates can be either positive or negative. This distinction is an important one for policy analysis: the positive, useful, and unobtrusive functions performed using mobile phones are not subject to much scrutiny by policymakers, while negative concerns and conflicts between forms of mobile media use are more likely to bring about demands for regulatory responses to manage, mitigate, or remove risks. Positive characterizations of mobile phone uses by children include the common observations that mobile phones are important devices for family management at a distance, a phenomenon referred to as, *inter alia*, remote-control parenting, mobile parenting, or mom-in-a-pocket. The coordination of family life via the mobile

phone is a common use of mobile phones, something increasingly important when parents are working and children are engaged in extra-curricular activities. Research has also found that, with some variation, emotional relationships are sustained via mobile phones: communication need not fulfill a practical task in order to be important. In addition, mobile phones are widely regarded as enhancing feelings of security for both children and parents by providing the potential for contact at all times.

On the other hand, there are a number of negative or problematic uses of mobile phones often encountered in the literature and in policy discussions. The kinds of negative impacts of children's use of mobile phones include, variously, risks of mugging, bullying, and happy slapping, the social pressure to have the "right" mobile phone, the potential for teenagers to engage in commercial sexual activity via mobile Internet sites, and mobile phone addiction. In addition, many parents consider the ability for children to be more secretive about whom they are communicating with to be a concern, although of course some children see this independence from parental surveillance as positive. Overall, despite the concerns and risks recognized, both parents and children tend to see mobile phones as having an overall positive impact on their lives.

Without a doubt, a significant body of research has demonstrated that mobile phones are an important factor in many young people's social and cultural lives. For many young people, the mobile phone has become an essential device in peer relationships and a contributing factor in their self-esteem. This raises a number of important issues for research and policy. One is cost management: mobile phones represent significant expense for young consumers, who are often economically dependent on parental sources of income.

In addition, though not well covered by the literature, is evidence of an emerging, intractable conflict between schools and families over the possession and use of mobile phones (Rizzo, 2008). Schools often see mobile phones as a nuisance, an impediment to their educational mission, and even a risk to students' safety. This can be a major concern for parents, who want to be able to contact their children while they are in school. It is also a concern for children, who may share their parents' desire for familial contact, and who of course desire mobile phones for other reasons. The conflict over children's use of mobile phones in school is a matter of increasing importance, as school systems have developed policies to regulate and limit mobile phone use by students. School policies address real problems with the disruptive force of mobile phone use, as well as responding to fears heightened by mobile media panics. The competing interests of schools, which seek to limit the potential for disturbance in the classroom, and those of students and parents, who desire constant contact, has required new policy responses.

Research and regulation on children's mobile media use also raises broader sociological and political questions. Importantly, the definition of childhood itself comes into question. How is "childhood" defined and understood in research and policy discussions regarding mobile media use? What ideas about childhood predominate today? What are the implications of particular social constructions of childhood for

mobile media policy? In order to answer these questions, we need to probe more critically into the various ways “childhood” has been conceptualized historically, the archetypical ideas that have endured, and the contemporary risks and anxieties associated with childhood, youth culture, and new media use.

Childhoods Past and Present

In contemplating the ways that childhood is understood in the present, it is advantageous to first examine the past. As British theorists of childhood Chris Jenks, Alison James, and Alan Prout (James, Jenks, & Prout, 1998; Jenks, 1996) have underscored, political philosophers Thomas Hobbes, Jean-Jacques Rousseau, and John Locke each contributed conceptions of childhood that accorded with their respective conceptions of human nature. These philosophers offer three versions of the child as the pure, essential, and unadulterated form of the human being: untamed (Hobbes), untainted (Rousseau), or untrained (Locke).

For Hobbes, life in its elemental state is uncivilized, unstable, brutish, and animalistic. Hobbesian childhood exists in a state of nature. Children, being as yet unschooled and untamed, needed to be brought, forcefully if need be, into the life of enlightened adulthood. Analogies have been made to colonial discourses of the savage native who needed to be saved (Jenks, 1996), and the wild animal needing to be broken (James et al., 1998). Childhood, in the Hobbesian, evil, devilish use of the term, is a period of life during which the authorities – parents, schools, the church, the law – ought not to spare the rod, lest the child remain spoilt.

Paired against the Hobbesian devilish child is Rousseau’s angelic child, who similarly resides in a pure state of nature, but one of prelapsarian blissful innocence rather than the bestial, savage, and sinful world after the fall. Jenks (1996) presents this, in contrast with Hobbes’s untamed Bacchic beast, as the Apollonian child, “the heir to sunshine and light, the espouser of poetry and beauty” (p. 73). Rousseau was as intensely enthusiastic about childhood as Hobbes was pessimistic. It is as though the loss of childhood, and of the innocence and pristine freedom associated with it, is to be delayed for as long as possible, and mourned when it arrives. The irony of this, of course, is that like Hobbes’s little devils, Rousseau’s little angels require the intervention and protection of the adult world, even if it is the adult world that children need to be shielded from. Hobbes’s little devils and Rousseau’s little angels share also the sense that children are born with a preordained nature, be it native and bestial, or natural and innocent. John Locke had other ideas.

According to Locke, children are not born with any innate moral characteristics. They are not even imbued at birth with human reason, but they do carry within them the potential to develop reason and should inevitably do so as they gain experience and turn potential into actual human rational thought. This implies that a major difference between children and adults is that adults have knowledge born

of experience whereas children have not yet acquired such knowledge. Adults are therefore placed in a position of intellectual superiority to children: it becomes the responsibility of adults (especially modern-day parents and teachers) to provide opportunities and guidance, through parenting and pedagogy, for children to become rational, moral, adult members of society. Unlike Hobbes, who suggested children were a risk to (or at least at odds with) society, and Rousseau, who saw society as ruinous to childhood, the Lockean view holds that “through education children will become rational, virtuous, contracting members of society, and exercisers of self-control. They will not threaten social order” (James et al., 1998, p. 16).

John Locke sits historically between Hobbes and Rousseau. The three together influenced philosophical and political thought from the early modern period through to the Romantic period and beyond. Together, their ideas about human nature, and about the relationships between the people and those who govern them, have had tremendous impact on Western political thinking. Their contributions to early modern conceptions of the nature of childhood, and of the relationships between children and the authorities that rule their lives, are equally pertinent, and remain so. Whether we regard children as “pure, bestial, innocent, corrupt, charged with potential, [or] *tabula rasa*” (Jenks, 1996, p. 31), we continue to contemplate them as subjects to parental and pedagogical forms of governance, discipline, training, and protection. We continue, in this way, to conceive of childhood as a period of political subjectification by the individuals and institutions of adulthood that hold sway over children’s lives – until, that is, they reach adulthood and, for better (Hobbes) or worse (Rousseau) or either or both (Locke), they become part of society and thus transition from presocial to social beings.

From these three great political philosophers arises a politics of childhood as apolitical, in the sense that children are not expected or able to participate in political society, yet also as politicized, in that they are subject to political authority. Childhood, in this sense, is a period of sociopolitical transition from subject to (partial) agent. How this apparent transition occurs, and the stages through which children become physically and psychologically adult (thereby attaining the right to take responsibility for their own lives at the age of majority), was to become the concern of developmental models of childhood.

The leading figure in the field of developmental psychology, and therefore of the naturally developing child, is Swiss psychologist Jean Piaget (Piaget, 2002). Piaget developed a theory of intellectual development through empirical studies of children’s use of information from their environment at different ages from infancy onwards. Piaget is best known for his influential theory of stages of development, in which children are thought to progress through a series of qualitatively distinct levels of cognitive, and thus intellectual, development. Piaget’s theory followed earlier developmental models that position children as lacking adult capacities – of autonomy, rationality, responsibility; as psychologically and emotionally dependent and vulnerable; and/or as “needy” for particular experiences and opportunities which, if not provided, will undermine the child’s proper development (Stainton Rogers, 2004,

p. 129). This highly influential formulation of childhood, following the important influence of Piaget, positions children and young people as developing as thinking beings, that is, developing new and different forms of thinking as they pass through developmental stages on their pathway to adulthood. In this model, children are once again regarded as adults-in-the-making, incomplete and insufficiently able to be (fully) responsible for themselves and others, thus requiring care, supervision, and discipline.

Jenks (2004) discusses how the model's appeal and its problems lie in the conceptualization of childhood as "normal" and "natural" (p. 79): we all experience childhood, so the argument goes, and see others (our children, our family and friends) as children and later as adults. Childhood is such a familiar, everyday, and intrinsic aspect of our experience of life that it is easily rendered normal and therefore "natural" in similar ways to which gender, ethnicity, and sexuality were once (and are still) considered in terms such as natural/unnatural. Herein lies the first major criticism of the natural developmental model from the sociological perspective espoused by Jenks and colleagues (James et al., 1998): by normalizing and naturalizing childhood, this period of life is made subject to the normative claims of the developmental psychologists and their adherents in the fields of medicine, parenting, teaching, and policy. Children must be, and must be treated as being, "normal."

In their critique of the development model of childhood, James, Jenks, and Prout (1998) identify childhood as a project to be managed by adults and undertaken by children under adult supervision. Children must learn the correct ways of intellectually and morally understanding and acting, at the right stages; adults must provide the pedagogic and disciplinary environment in which correct progress can be acknowledged and deficiencies addressed. The resemblances to other presocial models are significant: the emotional, uncontrollable id of the bestial, demonic child is a natural stage to be overcome with moral discipline and socialization; the innocent, pristine angelic child is a temporary state at odds (regrettably for Rousseau) with adult experience; and the tabula rasa is the opening stage of the child's development into, eventually, a rational, complete human being.

These models all share the notion of the child as incomplete – "becoming an adult" rather than "being a person" – and the sense that childhood is a time before we take our place in the world. Social theories of childhood, in comparison, see children as being in the world, in their own right.

The influence of the social developing, or socialized, child is highly significant when considering the politics of childhood. Political theory is often concerned with the ways societies are constructed and governed. In a functional sense, political theory situates individuals within society, each with particular roles to serve depending on the nature of that polity: as a subject to a crown in a monarchy, for example, or as a rights-holding citizen and participant in democracy, or as a member of civil society, or as all of these concurrently in a liberal-democratic constitutional monarchy like Australia or Japan. All must fulfill their role to keep society ticking over as best it can. Politics is also about the role of power: who governs, over whom, in

whose interests, and what maintains their rule as legitimate and effective. As such, the ways that society preserves structures containing those that rule and those that are ruled over relates directly to the reproductive models of socialization.

These models of socialization also share common features that, according to Jenks (2004) and James, Jenks, and Prout (1998), are inadequate for a social theory of childhood. For one, they have “little or no time for children” (Jenks, 2004, p. 88), in that they are mostly concerned with the adult world, its structures, functions, and reproductive process. Childhood is a time when pre-adults are fitted, or forced, into this adult world. Second, society is presented as a whole, complete, all-encompassing structure that subsumes the many differentiated and variegated groups within that entity. This macro-scale framing of social worlds and the members within them reduces all subgroups and subcultures to elements of a wider whole.

However, not all social theories of childhood are so inclined. Other social theories of childhood emphasize and investigate children’s social worlds from the starting point of the lives of the children themselves, and take as their base unit those social groups that are constituted by children themselves, such as gangs, “urban tribes,” and other youth subcultures (James et al., 1998; Jenks, 2004).

There is yet another construction of childhood, one that might be called post-structural childhood. Children in late modernity live in domestic situations that are characterized by diversity, fluidity, and instability, as well as being sites in which the traditional hierarchies are challenged by children more able to assertively claim roles in family decision-making processes: families grow precarious; children become precocious. Parents, less certain of their authority over their children, more swiftly make concessions to their children’s opinions and expressed desires, or – perhaps with less timidity yet with similar consequences – more fully recognize their children’s rights within their increasingly open and democratic families. There may be reasons to defer to children’s opinions: children may have greater expertise than their parents in the rapidly changing market for technology and consumer goods, for example. It may also simply be that parents and children are more likely to feel that respect ought to be earned and deserved, rather than simply claimed and assumed by parents from children (see Wyness, 2006, p. 55). Late modern families are seen in this contradictory way, as less stable and therefore less supportive of children while also being more liberal, participatory, and accommodating of children’s desires.

Yet, in a second contradiction surrounding childhood in late modernity, children may be seen as a source of tradition, stability, and surety in an otherwise destabilized world. Beck (1992) suggests as much when he refers to the relationship between parents and their children as “the last remaining irrevocable unexchangeable primary relationship” (p. 118). Wyness (2006) concurs and adds that being the last such prospect for certainty makes the value attached to such a relationship all the more acute, even desperate: “children’s dependence, obedience and their subaltern status become central to adults as they seek to re-centre themselves within a context of moral and social flux” (p. 53). As such, relations between the generations within the family are, in a curious case of late modern self-reflexivity, both the causes of instability and

anxiety, and the solution to such feelings of insecurity. Children have become a source of moral anxiety as well as a form of “moral rescue, a means by which adults try and recapture a sense of purpose and belonging” (Wyness, 2006, p. 53).

The consequences of such contradictory concerns within the contemporary family about childhood can be found in public policy and the proto-politics of family. The modernist project continues to dominate in areas of public policy, especially education policy, wherein children are measured against a “normal” childhood and prepared for an adult future, and schools are held accountable for their roles in achieving these fixed, measurable, performance-based goals. This contrasts with the relatively private world of the family, where the goals are less certain, or at least more diverse, and performances are difficult to measure. Another concern is the rise in parental anxiety about the risks associated with (late) modernity. Often these risks are associated with the trappings of modern life. One source of parental anxiety is the fear of violence or misadventure, perhaps at the hands of other children or (more pejoratively) youths during the lengthy commute to schools that are further from the domestic home than in the past. Another evident cause of concern is the exposure to inappropriate or offensive or even damaging material via the various forms of media.

Regarding both of these points – the contrasts between children’s private family lives and the policies of public life and education, and the increasing anxiety about the risks children face – the roles of mobile media have become crucial, and the responses to mobile media use have assumed greater importance. Mobile phones, as noted in the literature reviewed above, have become essential tools in the management of (private) family life, yet they are largely frowned upon and their use severely restricted in the (public) sphere of school education. Mobile communication has become a crucial aspect of many young people’s social inclusion among their peers, especially among post-elementary or primary school students for whom it offers also the prospect of greater autonomy from parental control. Yet mobile communication also offers the promise (if not always the reality) of parental surveillance of children. Parents regularly claim that their children are permitted to own and are provided with a mobile phone so they will be and feel safer, yet the dangers of cyberbullying, happy slapping, sexting, and the like are all associated with the malevolent potential of mobile media.

Moral Panics and Risks

Since Stanley Cohen’s seminal work, *Folk Devils and Moral Panics* (1972), a number of studies have examined the phenomenon of the “moral panic,” moments when particular behaviors labeled errant, dangerous, or deviant gain overblown attention. Such panics are typically associated with youth subcultures, which are viewed as posing a risk to others and to communities or culture in general. Such panics can

also arise when deviant groups or individuals pose apparent risks to children. Cohen's moral panic theory outlines the roles played by institutional authorities (such as police forces) in labeling certain behaviors and subcultural groups as morally dangerous. Through forms of mediated communications, especially the news media, these same authorities then amplify these concerns to a crisis level, which requires urgent, decisive action.

Although the intention appears to be to halt or contain deviant behavior, moral panics, suggest McRobbie and Thornton (1995), can in practice inspire further deviant behavior, in two ways. First, by communicating information about deviant behaviors to a wider population, more potential participants become aware of such behaviors, prompting experimental reproduction of these very same behaviors by those who might otherwise have remained none the wiser. Second, by associating deviant behaviors with subcultural groups, moral panics provide those who self-identify with these subcultural groups with reasons to experiment with or embrace the very behaviors that are being criticized. Along these lines, McRobbie and Thornton (1995) regard moral panics as a potential "culmination and fulfilment of youth cultural agendas in so far as negative news baptises transgression. What better way to turn differences into defiance, lifestyle into social upheaval, leisure into revolt" (p. 268).

Since the introduction of the concept some 40 years ago, moral panics have remained important for theorizing youth media use and representations of children and young people in the media (Buckingham, 2000; Goggin, 2006; Livingstone, 2002, 2009). The theory has recently been redeveloped and updated, as a result of a number of important developments: greater appreciation of the sophistication and complexities of the relationships between media and audiences thanks to studies in media effects; more sophisticated understanding of changes in the types of media and modes of media use thanks to studies in media ecologies; and significant contributions in this area coming from the study of social change and social movements.

Classic moral panics present a coherent, unchallenged account of the risks so-called folk devils pose to decent, normal society. McRobbie and Thornton (1995) suggest that the number and variety of media technologies, genres, voices, and audiences make it less and less likely that moral panic narratives will remain unchallenged. For example, young people are more able to challenge the narratives that portray them as immoral, and to provide counterdiscourses that render their subcultural behaviors as legitimate. Young people are able to make use of the proliferation of media and communications to create their own cultural spaces, away from the moralizing gaze of mainstream, adult authorities, often taking advantage of new media platforms to do so.

Additionally, young people can self-identify with so-called folk devils, willfully embracing the role of deviants as an act of rebellion. Moral panics of the past can also provide present rebels with model behaviors and attitudes. By emulating the deviants of the past, young people's transgressions are legitimized through appeals to nostalgia and tradition. Youthful rebellions of the past hold appeal for commercial actors seeking to attract consumers. As rebellion becomes marketable, it becomes

part of mainstream media, and thus further legitimized, or at least normalized within mainstream culture. Under these circumstances, behavior that is considered to be deviant and morally risky by some sections of the community has appeal for other sections of the community on the basis of anti-authoritarianism, either directly or because of the commercial appeal of the new and shocking. One person's moral degeneracy is another person's self-identifying, subcultural behavior, and another person's niche market of early adopters.

The analytic concept of risk provides some ways of addressing the limitations of moral panic theory. The risk society is one in which the developments of late modernity address concerns that have emerged from modernization, while generating further concerns that require further developments, and the cycle thus continues. All discourses of risk, Van Loon (2002) claims, are embedded in other forms of social discourse and dependent upon these other discourses for legitimacy and authority, in other words, for symbolic power. This is the case regardless of whether the risk being described is dependent upon discourses of scientific, measurable fact (such as environmental risks), economic modeling (such as financial risk), or game theory (such as the risk of international military conflict). Van Loon's (2002) emphasis is on symbolic association in the production of risks, and therefore of symbolic power in the politics of addressing risk. In the following cases of policy debates surrounding children's mobile media use, I examine the discourses of childhood and youth (such as the "devils," "angels," and "blank slates" discussed above), considering how the symbolic power of the risks associated with children's mobile phone use is dependent upon these discourses.

Examples from Japan: Facing the Future of Communication

Osaka Prefecture Governor Toru Hashimoto is neither the first nor the last in a long line of Japanese public leaders to call for a total ban of mobile phones from Japanese elementary and junior high schools. But he was the first to threaten, in December 2008, to enforce the ban in all schools under the remit of the Prefectural Board of Education. Osaka city and Sakai, both in Osaka Prefecture, have separate Boards of Education, and Hashimoto has urged both of these to follow his lead. Responding to declining poor educational performances and cyberbullying, pointing to private surveys and media polls that cite parental support for the ban, Governor Hashimoto's plan to rid schools of the dreaded *keitai* seemed on fertile ground. Concessions would have to be made. Children with two working parents might have to be allowed *keitai* so they can be monitored. Moreover, Governor Hashimoto admitted, not all children would likely obey the ban. But the essential message remained: the *keitai* was to be no longer an accepted element of children's lives, let alone an essential one, as Matsuda (2009, 2010) has suggested.

Previously, in early 2008, the prefectural Department of Education had undertaken a study in Hyogo Prefecture in response to similar concerns to those of Governor Hashimoto. Concerns to be addressed included the production of unofficial school websites, bullying and harassment, Internet dating leading to *enjo kosai* (teenage prostitution),⁶ and so-called “Internet addiction” blamed for lack of sleep, poor scholarly performances, and declines in communicative and social skills (Matsuda, 2009, 2010). In particular, cyberbullying and harassment were cited as being of a particular problem, such as unresolved quarrels or insults traded on *keitai*; posts on Internet bulletin boards (whether accessed on *keitai* or on a desktop computer) that escalated into hostility; and forms of harassment that occurred on *gakko ura saito* (unofficial school websites).⁷ The suicide of a senior high school student in Kobe, the capital of Kobe Prefecture, in September 2007 formed part of the premise and context for the study.

The study centered on a survey of 11,675 students and 10,253 parents, sampled from all public elementary schools, junior high schools, and senior high schools in Hyogo Prefecture (Research Group for Bullying Problems in Society, 2008). The subsequent report emphasized the need to empathize with children, and to teach both media literacy and media ethics as part of the more general approach to teaching ethics and moral reasoning in the curricula. In general terms, the report’s authors, including Professor Tomoyuki Okada from Kansei University, recommended approaches to education that emphasize emotional and moral learning, that promoted public (especially parental) trust and confidence in the schools’ role in instructing children in morals and manners, and that developed programs relevant according to their “stage of development.” It emphasized programs that introduce and develop skills and values training for elementary school students: “It is very important to give such instruction to elementary school children as some children start to use a mobile phone at this age” (Research Group for Bullying Problems in Society, 2008, p. 17).

The report’s recommendations for staged instructions are (my translation):

Lower grades of elementary school:

Foster sensitivity toward, and care for, other people who are far away, by including writing activities such as writing letters or postcards.

Higher grades of elementary school:

Teach the importance of keeping promises when communicating using information technology by making children think about manners and rules through actually exchanging emails and posting messages on message boards within the school, using the school intranet.

Middle school:

On the Internet, we sometimes use words or expressions that we would not normally use face to face, since we can exchange information without seeing the person in question. This can result in them being hurt, perhaps inadvertently. It is important to teach students to consider how others feel when receiving these messages, and to increase their awareness of human rights.

Teach students about the risks and responsibilities that come with their messages, and about the possibilities of violating laws because of what they write.

High school:

Through teaching the students about the laws that are relevant to online communication and exchange, get students to consider the responsibilities they should take on in exchange for sending information freely.

Demonstrate, using actual examples, the possibilities of unintentionally becoming an assailant over the Internet.

Ask students to analyze objectively why they wanted to bully or slander others on the Internet. After that, teach them the importance of thinking assertively, as well as of thinking about others' responses. (p. 17)

Much of what is recommended in the report does not differ significantly from what one might expect when generally discussing the responsibilities of ethical and considerate behavior. It does, however, take into account the specificities of mobile mediated communication, including the asynchronous and non-co-present aspects. For example:

It is advisable to foster compassion and sympathy for others' feelings, and a sense of gratitude within children in their daily life, so that they come to think about the feelings of users/readers of blogs or emails who they cannot actually see. It is also important to teach children the fact that communication on the Internet or by email can unintentionally hurt people deeper than verbal communication. (p. 17)

The report also suggested that schools work more closely with the parents as part of the school community to assist with this task outside the classroom.

The Hyogo Department of Education that commissioned the study did not adopt the report's recommendations. Instead, it called for a ban on *keitai* in elementary schools and junior high schools. Where possession of a *keitai* was unavoidable, the functions of the device were to be limited to voice calls and location-based GPS functioning. In a presentation discussing this in July 2008, Professor Okada described it as being akin to epidemiological approaches that seek to protect those at risk of contagious disease by preventing them from exposure and the subsequent risk of infection. He noted that this contradicted education-based models that had characterized the Japanese government's promotion of information and communication technologies (ICTs).

Governor Hashimoto's determined call for a total ban of mobile phones in elementary and junior high schools in Japan was supported publicly at the national political level. Key supporters included the Chief Cabinet Secretary Takeo Kawamura, Education Minister Ryu Shionoya, and the Minister for Internal Affairs and Communication (SUOMO), Kunio Hatoyama. Ironically, Minister Hatoyama's portfolio included development and promotion of the U-Japan policy that endeavored to make information communications technology a full-time, always-on, unobtrusive, and welcomed part of everyone's lives. This priority for full-time connectivity included

elementary schoolchildren, as explicitly addressed in the U-Japan online promotional material (see Spry, 2010).

In one particularly telling vignette from the website promoting the U-Japan policy and its vision of the future, SUOMO suggests how generations will be able to maintain social relationships at a distance while going about the busy business of modern family life. This is the story of Ayaka Tanaka and her busy mother. The opening scene shows Mrs. Tanaka, dedicated office worker, trying to organize another hectic schedule of client demands and meetings with colleagues. Seeing that her day may run away from her, she gives thought to that night's meal and wonders if she has enough ingredients at home. A screen appears seemingly at will. This is a "ubiquitous terminal": Mrs. Tanaka's portal into the U-Japan world of connectivity and convenience. She quickly consults her fridge, which informs her that a number of items have passed their expiration date, and suggests she buy some rolled cabbage. Online food sellers are connected, so the fridge suggests that Mrs. Tanaka order some organically grown cabbage from the Net Market. Thinking to herself that Ayaka will like that, Mrs. Tanaka agrees, and also tells the fridge to order anything else it thinks they need. Later, as the working day develops, Mrs. Tanaka again contacts her home through a ubiquitous terminal and sets her arrival time for 7 p.m. She asks the terminal to check that Ayaka is at her scheduled piano lesson. The piano school has some surprising and troubling news: Ayaka is absent. Mrs. Tanaka urges the terminal to immediately search for her. Ayaka is tracked and swiftly located in the Botanical Gardens, far from where she is supposed to be. Mrs. Tanaka straight away connects with Ayaka, whose face appears on the screen.

A surprised Ayaka answers, and a conversation begins tersely. (Ayaka: It's you, mommy!? What's wrong? Mrs. Tanaka: What do you mean, "What's wrong?" You're supposed to be at your piano lesson!) But rapidly it becomes clear there is no cause for alarm. (Ayaka: But today's the school field trip to the Botanical Gardens. Mrs. Tanaka: Oh, is that today?! I'm sorry. I'll make you a special dessert tonight. Be careful on your way home. Ayaka: Yes, mommy.) Ending the conversation, Mrs. Tanaka returns to her work. This, according to the Japanese government, is the future under U-Japan. It is a place where mothers can monitor and contact their children any time and from anywhere.

In responses to children's mobile media use in Japan, a series of contradictions is readily apparent. Indeed, it would be difficult to imagine a more diametrically opposed set of policy positions. Moreover, these apparently contradictory responses arise from within a shared political discursive space. In one case, from one set of data and analysis, we find the Hyogo Board of Education's research findings. And in another case, contradictory responses have emerged from a single ministerial portfolio. That conflicts arise in politics is news to no one; that diametrically opposed conclusions are reached from the same data, or from the same political office, is perhaps a little more curious. How might one account for such contradictory responses?

James et al. (1998) caution that presociological views are not to be dismissed, if only because some persist in the public imagination: "they are models which

continue to inform everyday actions and practices alongside more sophisticated sociological theorizing about childhood" (p. 21). These views of children and the young include the Hobbesian "evil child" born into sin and therefore uncontrollable, needing, through processes of surveillance and discipline, to be domesticated or civilized (nature requiring taming), and, mirroring Hobbes, Rousseau's naturally good child, innocent and as yet unblemished by worldly experience.

In this light, the contradictory pronouncements of the proponents of public policy seem more understandable, even logical, and perhaps inevitable. For if children with mobile phones are potentially and actually becoming more distant from adult authorities and institutions, they become vulnerable and at risk to a public and adult world. These angels require protection, meaning surveillance and discipline. Also, when children with mobile phones are seen as escaping the bonds of parental and institutional discipline, they are seemingly revealed as potential dangers to themselves and other children.

The mobile phone is seen as contributing to the problem but it is also how these concerns are addressed. The mobile phone leashes children to the parents. It makes them, potentially, contactable and under surveillance (with its dual meanings of care and control), and this is very reassuring. For parents, this is one way of keeping their angels close within the private realm of the family. For public policymakers, this poses a problem. For if families can use the mobile as a management tool (Matsuda, 2009, 2010), schools may find it more difficult to do so. For schools, the mobile phone is a private possession of the students, who use the device for private uses.

But schools are not private in the sense of being spaces for individuals or families. They are communal spaces. Collective rules apply equally to all, or at least they are intended to. But children are also protected from a larger public world in school – the world of adult life. As such, for educational policymakers, the mobile phone presents the means for the individual and family to invade its space, and provides the means for students to escape the bonds of its space and its rules, bringing in the wider, more unruly, and less "childlike" world of violence (including harassment) and sex. This is not to suggest that policymakers are claiming schools have previously been free of sex and violence, merely that mobile phones exacerbate the problem. Denied the reassurances of constant contact provided to families, educational policymakers can be forgiven for seeing mostly risks to pedagogical aims and the educational environment. Put another way, the school and particularly the classroom are contested spaces, and school time is contested time. As this time and space is challenged and violated via the communicative capacities of mobile media use, a new mediated environment emerges, one in which the child becomes not only a teacher's student and a colleague of classmates, but also a child of parents, a victim or perpetrator of bullying, a consumer of popular culture, and so on.

The contradictory responses to children's mobile phone use – banning on one hand, moral education on the other – are pointed to in one of Qvortrup's (1993) general contradictions of childhood: "Adults agree that children must be educated to freedom and democracy, but society's provision is given mostly in terms of

control, discipline and management” (p. 9). If we take freedom and democracy to include responsibilities to one another as citizens, then the media moral literacy program suggested by the Hyogo research team exemplifies the first half of this contradiction, while the call for, and monitoring of, Governor Hashimoto’s ban on mobile media possession exemplifies the other half. The uses of mobile media by children and young people in Japan continue to provoke contradictory political responses, and these contradictions can be read as expressions of political attitudes toward both childhood and technology. I now turn to the similarities and specificities of two Australian case studies on children’s use of mobile media.

Examples from Australia: Threats and Opportunities

Outside Melbourne, in the southern Australian state of Victoria, lies Werribee. In June 2006, a girl, aged 17, met two boys as agreed at the Werribee Station. Taken to a nearby park, she was faced by up to 14 boys aged 15 to 17. There she was abused, sexually assaulted by two of the boys, and humiliated. One of the boys filmed the incident using a digital camera on a mobile phone. This footage was later combined with footage showing some of the boys making chlorine bombs, throwing eggs at taxi drivers, and dropping flares on a homeless man, as well as footage of them fighting at local parties and media clippings of other incidents the boys claimed to have been involved in. DVDs of this home movie were sold in nearby schools for \$5 each.

The consequences of the filming and distribution of the assault were highlighted by Elaine Crowe, President of Parents Victoria: “Technology can worsen bullying behaviour because it makes it more public. Victims are humiliated not just by the personal humiliation, but also when incidents are broadcast on the Internet or DVD” (cited in Miletic, 2006, at paragraph 32), adding that she considered those who viewed the footage also “morally culpable” (paragraph 33).

Twelve boys were arrested and charged with a range of offenses. Eight of them pleaded guilty to charges of sexual penetration by intimidation, assault, and producing child pornography and were convicted on November 5, 2007. Three others were later found guilty of the same charges on February 12, 2008. The judge noted that the making and distributing of a DVD of the assault had compounded the offense by adding to the significant physical and emotional trauma suffered by the victim during the incident (O’Keefe, 2007).

None of the boys received a custodial sentence. They were placed on youth supervision orders or on probation. The judge noted their guilty pleas, their remorse at the hurt caused, and their willingness to participate in a sex offenders program. In circumstances described as difficult at best, Alan, the father of the young victim, later agreed to talk about his response to the boys’ sentences. “We feel it matches the young persons’ needs at this time of their life,” he said. Adding, with regards to

the young sex offenders program, "It's a very intensive program, it has a high success rate of reducing adolescent sexual crime. It's education-based, it really helps young males connect better with their understanding of their masculinity and that's what they need more than anything as far as our family is concerned" (Smith, 2007, p. 9).

Other incidents of filmed violence reported in the Australian press around this time often referred to the Werribee events, the common factors in the reported assaults being youth, violence (often, but not always sexual), and the use of mobile phones as recording equipment. In one incident, two girls were recorded assaulting a third girl (it is not clear by whom). In another, three young men first harassed a taxi driver, then, when an observer sought to intervene, turned on him, assaulting him while a fourth member of the group captured the attack at close range on his mobile phone video camera. Media reports noted police concerns that recording the events had particular attraction for the perpetrators: "There's a trend, particularly with young people, towards finding pleasure in the video recording of such incidents," noted Detective Senior Constable Bodsworth (quoted in Russell, 2007, p. 2). "The disturbing part is that they go on to post the video footage of the incident so others can gain pleasure or some shock value from it [. . .] The callousness of recording (the incident) while another person is on the ground being beaten is appalling" (p. 2).

These events, and their coverage in the media, articulate a set of key concerns about young people as mobile media users. The first of these is risk: the young mobile phone user, in this sense, is a potential risk to the safety or well-being of others. The suggestion here is not that mobile phones themselves lead to more violence, but that the act of recording the bad behavior and later sharing it with others becomes part of the motivation for that behavior. In this case, the mobile phone is not a device that keeps young people safer or more secure, despite this being a significant parental motivation for getting mobile phones for their children. Echoes of Ulrich Beck's risk society are invoked in this representation of the mobile phone as exemplar of the way the trappings of modern life have become the very things producing insecurity and reducing safety.

When the mobile phone appears to be used in ways that victimize others and increase vulnerability – for example, exposing children to sex and violence – anxieties and moral panic predominate. Labeling these cases instances of moral panic is not to suggest that these actions are not actually happening or do not result in real harm to individuals. Even if the true scope of the problem is overstated by media reports, the cases themselves deserve attention in terms of their implications for young people's use of mobile media. As Goggin (2006) has noted, "bullying via the instrument of the cell phone remains almost exclusively something that is associated with children and young people" (p. 118).

The events in Werribee brought to the surface some of the deepest fears regarding youth mobile phone use: untamed youth as devils, innocent children at risk, and the role of media in the corruption of young people. In another, very different, example, the place of new and mobile media in children's education evoked a similarly passionate response in public debate.

On July 25, 2008, Diedre Coleman's 9X English class at Presbyterian Ladies' College, a private high school not far from the center of Australia's largest city, took the concept of the open book exam a step further than usual. Cognizant that books are not the only media from which information can be obtained, Coleman extended the concept to become an "open interactive technology" exam. The students prepared by considering sources of information and evaluating their appropriateness. Once in the exam, the students were given 40 minutes with which to complete the task. They were able to access any Internet site, any social networking site, were able to "phone a friend" or use iPods and mp3 players, and they could use headphones to access information or to block out noise from other students. The students were told to expect movement and noise from the others, although noise was to be kept to a minimum and they were not allowed to talk to one another. Once seated and prepared, they received their assignment, as follows: You are to write a sonnet. The subject of the sonnet is teenage love.

After they completed the assignment, the students were asked to reflect on the exercise and offer some remarks for the school's internal evaluation. Some of the responses include the following (quotations from personal communication, Presbyterian Ladies' College, March 10, 2009):⁸

I have learnt a lot from this experience, not only about the limitations of technology, but also how to manage masses of information in small periods of time [. . .] It has taught me about working under pressure and what works best for me in this situation. If I could do the assessment again, I would probably stay more focused because, at the beginning, I spent about 10 minutes looking for websites which I didn't use.

Next time I think I will try to be more open minded about the choices I make and try to include everything instead of just taking the obvious route (computer/internet) and not utilising everything I could.

I organised to phone a close family friend although in the end she didn't answer her phone on the day, so the plan went out the window.

I called my Auntie who is quite good at English. She helped me to brainstorm ideas and allowed me to start writing my sonnet. I found this very useful as she was prompt in returning my phone calls and gave me feedback about aspects of the sonnet.

When this experiment was reported in the daily broadsheet newspaper, the *Sydney Morning Herald* (Patty, 2008), the responses on the accompanying blog were, expectedly, almost all diametrically opposed along lines that are now familiar. One group responded by bemoaning the exercise as an expression of the decline in educational standards – new media use associated here with the decline of literacy – and hence a decline in cultural standards and further evidence that modern education was not adequately preparing students for the future as productive citizens. Some examples of this sort of response included:

Yet another example of society not making kids responsible for their own action. Looks like I will never get to retire, as the next generation will not be able to think for themselves.

This is absolutely ridiculous. Education is about preparing children for adulthood. Sorry PLC Croydon, but you have failed. If a student does not develop a decent study/work regime, what good will they be at University and then in the workforce? (SMH Online, 2008)

Others saw the process as open to abuse, either through cheating or by unfair advantages for those with access to expert knowledge:

A lot of kids don't have mentors outside of school or relatives who they can "brainstorm ideas with." For example kids who migrated from a foreign country whose parents don't speak any english, whose relatives dont speak any english. Who are they going to call to brainstorm ideas with? The rich kids with educated parents will do well but noone else. (SMH Online, 2008)

On the other hand, some were supportive of the task, noting that it reflected the skills and knowledge required outside of formal educational institutional environments:

I am a manager with a number of staff. I don't require them to memorise everything, but I do need them to be able to research information, analyse it and use it to support whatever project we are implementing. People with strong skills in researching (ie via internet, books and people), analysis (eg using tools such as statistics) and writing (to produce reports, documents, policies etc) will do well in any workplace. People with excellent writing skills are highly valued. Given this, I think PLC is on the right track. Exams based on memory only are no longer relevant for the world we live in.

A+ This is exactly what professionals, tradespeople, and everyone else does in the real world. Finally education is creeping into our schools! (SMH Online, 2008)

Others, adding their support, also took umbrage with the notion that this task was not developing learning skills:

Another key point missed by many here is the concept of "Core Skills." In what is becoming a more diversified work place where multi-tasking; changing career paths; and professions with ever changing underlining theory of practice and technology is becoming the norm (what you learnt at school 20 years ago is not what children are learning today), "Core Skills" are becoming increasingly more important. For those who aren't aware of core skills; they are attributes such as inter-personal communication (phone a friend); research skill (internet/databases); critical analysis (knowing what is relevant to put on your IPOD); problem based learning (learning how to solve a problem beyond recalling what is locked away in your brain) etc. (SMH Online, 2008)

These contrasting responses to the "Phone-a-Friend" news story are characteristic of the public discussion and political attitudes toward young people and media. They are also characteristic of another typical tendency – namely, the absence of, or dis-

missal of, children's voices in the debates that concern them. This is particularly evident in the responses of those who bemoaned the supposed decline in cultural standards they feared would result from this form of educational practice. The students themselves, as is demonstrated in their responses, took a more circumspect and pragmatic approach. Similarly, Alan, the father of the Werribee assault survivor, presented a pragmatic, tempered, and humane case for proportionality, if not moderation, regarding the boys' punishment, in contrast to many public calls for much harsher sentencing. He reserved his criticism for those who had been insufficient, in his view, in their responsibility for the welfare of his daughter.

Giving voices to children in these public debates about the politics of mobile media is not straightforward or easy. In the Werribee case, the girl's right to privacy and protection from further harm makes it difficult to expect her to respond, and in any case it is likely that her concerns would differ from policymakers'. The opinions of students surveyed in Hyogo (and their families) could have been taken further into account but were easily dismissed by policymakers. The students from PLC seemed to contribute to public debates and internal school feedback about the assessment task they participated in, but again, their contributions seemed to be ignored by policymakers.

Comparing Japan and Australia: Commonalities and Contexts

The examples in this chapter were not selected because they provided material for cross-cultural comparison but because they illustrate a range of instances in which mobile media use by children and young people has been politicized. Still, taken together, the examples from Japan and Australia demonstrate some significant similarities and some notable differences. One of the most compelling similarities is how important mobile phones have become for the management of family life in both Australia and Japan. This is evident in the examples shown here and also in comparable literature and research (such as Matsuda, 2008, 2009, 2010; New South Wales Commission for Children and Young People, 2009). Mobile phones have become firmly entrenched as essential devices for family communication and coordination. (This is demonstrated in the representation of family life in the example from SUOMO's promotion of U-Japan: seeking a positive aspect of children's access to mobile communications to showcase its policy, the Japanese government chooses the mother-child relationship.) Research in similarly affluent societies supports this finding (Devitt & Roker, 2009; Rakow & Navarro, 1993; Rizzo, 2008).

Certain themes in the representation of youth mobile use are also evident in these case studies. First, commonly held fears about the impact of mobile media on children's lives include those related to exposure to sex and violence. There are, however, different sets of mobile media that are associated with these behaviors: *enjo*

kosai is not unique to Japan (similar practices have been reported in South Korea and the global cities of East Asia [see Spry, 2008]), but it is not as much a concern in Australia, where “sexting” – the sending of sexually explicit messages and photographs via mobile devices – is the main activity prompting public distress and political responses (New South Wales Government, 2009). Likewise, the attempts to profit from the filming and distribution of the sexual humiliation in the Kings of Werribee example does not have an equivalent in the Japanese examples chosen, although that does not rule out the possibility of its occurrence. The acts of cyberbullying cited in the Hyogo research do seem roughly analogous to concerns raised in the Australian context, as do the concerns that mobile phones are a distraction from the “proper,” more traditional and accepted forms of educational practice.

A notable difference between Australia and Japan is the public call for bans on school-aged children owning or possessing mobile phones by several leading Japanese politicians. Similar calls have not been made in Australia, at least not to the same extent. This may be a product of the different political cultures. Australia is a liberal democracy with strong anti-authoritarian tendencies, and Australians are much less likely to accept direct government intervention in a matter they would regard as a private concern. Many Australians would view any such intervention as overreach by an intrusive state. Japan, on the other hand, has a history of state intervention in the schooling and moral education of Japanese children, going back to the Meiji restoration and including the reforms of the post-World War II era. The Japanese citizenry would be more familiar with (and possibly more accepting of) state calls for “improved moral health,” such as those implicit in the mobile phone bans. This important difference between Australia and Japan underscores the importance of local and national cultures in the politics of youth mobile media use.

Overall, there were important similarities in the representation of children as immature or risky media users. It appears that the moral panics identified by David Buckingham (2000) and Sonia Livingstone (2002, 2009) with regards to youth media use in the United Kingdom are evident also in Japan and Australia. (Regarding Australia’s similarity to the UK context, see Goggin, 2006.)

Back to the Futures: Conclusions and Questions

What becomes apparent in a variety of ways in Australia and Japan is that mobile media present challenges for techno-dystopians, who see new media as the source of new risks and moral hazards, and opportunities for techno-optimists, who see new media as having brighter, more creative and democratic prospects. It also brings into sharp relief the role of ongoing normative notions of children, raising questions about how the key institutions of the family and schooling negotiate children’s mobile media use. Public discussion of children as mobile media users remains strongly informed by past constructions of childhood, from Hobbes through to

Piaget, which present children as only partially formed human “becomings,” not as complete human beings.

A common refrain is that children are the future. This cliché turns children into possessions, and burdens them with hopes for, and fears of, the future, including the future of communications technology use. Children become the symbols of what humans are turning into; their use of media called in evidence of the way things are to become. Entire generations are marked out as either indicators of social decline – “the dumbest generation,” according to Bauerlein (2009) – or as pointers to a brighter, techno-utopian tomorrow via the technologically savvy “digital generation” (Tapscott, 2009). And while there are a number of sophisticated approaches to children as creative and engaged (if imperfect) media users (Buckingham, 2000; Livingstone, 2002, 2009; Montgomery, 2007), there unfortunately seems to be little room for nuanced understandings of these issues in public debate.

Moreover, seeing children as the *future* can deny children their *present*, limiting their capacity to participate in public discussion and political decisions that affect the future of media. There are a few exceptions to this exclusion. The students from PLC, as I mentioned, were able to participate in the online debate, and in the internal review, about the “open technology exam,” but it was unclear how seriously their views were taken. Compared with the views of professional teachers and departmental staff, and of course parents, the views of children are easily dismissed. In another case (New South Wales Commission for Children and Young People, 2009), school-children were invited to participate in research investigating their views and experiences with mobile media. I was a researcher on this project, and this chapter is in part a result of my participation. The experience was instructive: conducting research with school students requires the permission of a number of gatekeepers, including university ethics committees, government departments, high school principals, teachers, parents, and, lastly, the students themselves. The research was instructive and offers one of the few examples of the directly expressed views of young mobile media users in educational contexts (New South Wales Commission for Children and Young People, 2009). Rich Ling (2001, 2005, 2008), Larissa Hjorth (2009), and Misa Matsuda (2008, 2009, 2010), *inter alia*, have also done important research with young mobile media users, usually in social or family contexts. Still, research is developed, funded, designed, carried out, reported on, and eventually offered for the consideration of adults in authority (see Spry, 2012). These research efforts suggest that there are ways to include the voices of children in public debates about their lives, yet also highlight how rare and difficult it is for these voices to be heard.

NOTES

- 1 I use the term mobile media to highlight the uses of the mobile phone that extend beyond telephony to include SMS (short message service) messaging, emailing, accessing the World Wide Web, digital photography, and so on (see Goggin, 2006; Ling, 2005). I use

- the term mobile phone interchangeably with its equivalents from North America (cell phone) and Japan (*keitai*).
- 2 Elementary school, as it is known in the United States of America and Japan, is referred to as “primary school” in Australia. Both systems roughly cover ages 5 through 12. I use the terms interchangeably, dependent on the country in question.
 - 3 See Green (2003); Johnson (2003); Goggin (2006); Grinter and Eldridge (2001); Ling (2005, 2008); Matsuda (2005); Taylor and Harper (2002, 2003); Weilemann and Larsson (2002); Wynn and Katz (2000); Yoon (2006); and Hemelryk Donald and Spry (2007).
 - 4 See Goggin (2006, 2010); Habuchi (2005); Dindorfer Anderson (2010); Hemelryk Donald and Spry (2007); Spry (2010); and Castells et al. (2007).
 - 5 See Matsuda (2008, 2009); Rakow and Navarro (1993); Geser (2004); Davie, Panting and Charlton (2004); Rizzo (2008); Ribak (2009); Christensen (2009); and Devitt and Roker (2009).
 - 6 *Enjo kosai* is a practice wherein young Japanese girls, usually in high school or younger, arrange meetings with (typically) older men and participate in social activities like dinner or karaoke up to and including sexual acts, in exchange for money or gifts of expensive designer goods like jewelry, clothes, or perfume (see Spry, 2008, 2010). Aside from the concerns about minors engaging in sexual acts, reports of violence raise further concerns. According to the National Police Agency, in 2008 “the number of people who became crime victims after using dating sites [. . .] included 328 high school students, 211 junior high school students and two elementary school students. Of those under 18, 714 people, or 98.6 percent, accessed dating sites via cell phones” (“Net profile sites new threat to kids,” 2009). The same report notes that online sexual predation may be moving from dating sites to social networking sites.
 - 7 These sites typically include photos and commentary on colleagues, friends, and staff members of the school of those students who set up and contribute to the site.
 - 8 The names of the students have been withheld. These quoted responses, as well as the information about the exercise, were provided via email by Presbyterian Ladies’ College.

Artificial Life on a Dead Planet

Charles Thorpe

ABSTRACT

In this chapter, Charles Thorpe argues that the trajectory of capitalist technology is toward artificial life on a dead planet. The destruction of ecosystems and species by deforestation, chemical pollution, and the effects of climate change is being accompanied by a parallel process of the creation of artificial forms of life. We currently face crisis in all the systems that sustain life on this planet: from the oceans, to the soil, to the atmosphere. But as capitalist industry devastates the existing natural world, capitalist-aligned technoscience brings into being new forms of autonomous or lifelike technologies. The devastation of existing ecosystems and the construction of lifelike technologies are interrelated developments that are rooted in capitalist dynamics of alienation, reification, and subsumption. Just as, under capitalism, human life-activity is transformed into abstract labor, the productive and reproductive capacities of living things are transformed into abstract life. Life is eviscerated, simplified, and reified, while the powers of the living are transferred to capital. At the same time that the living world is in a state of crisis, capital is becoming increasingly lifelike.

Introduction

No one today remembered why the war had come about or who, if anyone, had won. The dust which had contaminated most of the planet's surface had originated in no country and no one, even the wartime enemy, had planned on it. First, strangely, the owls had died [. . .] After the owls, of course, the other birds followed, but by then the mystery had been grasped and understood. A meager [extra-terrestrial] colonization program had been underway before the war but now that the sun had ceased to shine on Earth the colonization entered an entirely new phase [. . .] Under U.N. law each emigrant automatically received possession of an android subtype of his choice [. . .] That had been the ultimate incentive of emigration: the android servant as carrot, the radioactive fallout as stick.

(Dick, 1999, p. 15)

Philip K. Dick's science fiction masterpiece, *Do Androids Dream of Electric Sheep?* (1968), presents a future in which most of Earth's species have been wiped out by radioactive fallout and the human survivors are fleeing a ravaged Earth. Survival on the inhospitable terrain of other planets is made possible by android slave labor. For those who cling on in Earth's decaying cities, possession of a live animal is highly coveted, due to the fragility of biological life on the planet and the scarcity of animal life. The majority who cannot pay the premium for a live animal accept as second best an android replica of a sheep, a snake, or an owl.

Science fiction frequently couples artificial life with ecological devastation, violence, and the destruction of human life. Movies like *The Terminator* or *The Matrix* present an eviscerated Earth covered in scrap metal and stalked by machines, and scenarios of biotechnological experimentation gone awry have been the premise in films such as *I Am Legend* and *28 Days Later*. These films reflect a cultural undercurrent of unease that contrasts with the techno-hype current in our universities and among our policymakers.

Margaret Atwood's novel *Oryx and Crake* (2003) portrays a world in which, as the Earth's species face extinction, corporate laboratories are turning out new genetically engineered life-forms, such as pigs with human internal organs. The corporations also are boosting demand for their pharmaceutical products by surreptitiously producing new diseases. Atwood combines imagery of sterility, extinction, and death with the portrayal of the uncontrollable overflowing of bizarre new life-forms. Life takes new forms, but in ways that offer bleak prospects for the continuation of *human* life.

As Daniel Dinello (2005) has argued, such science fiction visions of technology out of control can no longer be dismissed as mere sensationalism or paranoia. Rather, these fictional scenarios can sensitize us to dynamics that are institutionally embedded and have political and economic power, but which are also the source of pervasive social anxiety. Such dystopian and pessimistic forms of science fiction offer a useful counter to the breathlessly optimistic, utopian language in which technologies such as nanotechnology and robotics are framed by their proponents (Dinello, 2005,

pp. 1–17).¹ What, then, is the critical significance of these couplings of artificial life with the destruction of life? Do these combined images reflect real-world developments? If this is a warning, is it about technology itself, or about a more fundamental dynamic in our social relations and social organization?

Today, the destruction of ecosystems and species by deforestation, chemical pollution, and the effects of climate change is indeed being accompanied by a parallel process of the creation of artificial forms of life. We currently face the evisceration and breakdown of all the systems that sustain life on this planet: from the oceans, to the soil, to the atmosphere. But as capitalist industry devastates the existing natural world, capitalist-aligned technoscience brings into being new forms of autonomous or “lifelike” technologies.

In his famous missive in the year 2000, “Why the Future Doesn’t Need Us,” the computer scientist Bill Joy used the term “GNR technologies” to designate the converging fields of genetics, robotics, and nanotechnology – scientific fields that produce technologized forms of life or lifelike technologies. Joy warned that what is new in such technologies is the potential for “uncontrolled self-replication,” which poses the “risk of substantial damage in the physical world” (Joy, 2000). In the mid-twentieth century, the philosopher and sociologist Jacques Ellul used the concept of “the self-augmentation of technique” to designate the way in which large-scale modern technological and instrumentally rational systems (such as nuclear power) build their own internal momentum and escape social control (Ellul, 1964, p. 85). What is striking today is the fact that this autonomy of technology is no longer merely metaphorical, designating a loss of control by human beings over our collective creations. The goal of science and engineering in the GNR fields is to produce technological forms that are literally and concretely autonomous: robots that act independently of human command, or new manipulated or synthesized living things – technologies that appropriate the ability of living things to reproduce and multiply.

In an essay discussing the meaning of the android in his fiction, Dick observed that “the greatest change growing across our world these days is probably the momentum of the living toward reification, and at the same time a reciprocal entry into animation by the mechanical” (Dick, 1995, p. 212). This offers a profound insight into contemporary capitalist technoscience. The reification of the living as resource or commodity and the transformation of living organisms into productive machines is today accompanied by the animation of the non-living. Life is reified as it is subsumed within commodity relations and the cash nexus. The living world is integrated within capitalism as a stock of resources to be exploited and as a sink for pollutants. The consequent intense exploitation and waste are largely responsible for the unprecedented human degradation of the natural world and assault on the conditions for life that we are witnessing today. This degradation of the natural world combines with the intensified subsumption of nature and of life itself within capital: the transformation of the living world so as to shape the reproductive capacities of the living according to the timescales and efficiency norms of capitalist production. The result of these processes is a vast simplification in the natural living world:

the degradation of the Earth's ecosystems, the loss of biodiversity, and the imposition of standardized agrobusiness monoculture. As in Atwood's *Oryx and Crake*, this destruction of natural diversity is indeed accompanied by at least the promise of a proliferation of new forms of life, engineered or synthesized living organisms and lifelike machines. A dead planet and artificial life therefore represent twin trajectories of contemporary capitalism.

From Abstract Labor to Abstract Life

In order to make sense of the contemporary interpenetration of life and technology, we must come to grips with how life is used and transformed within our productive and social relations. Karl Marx argued that the capitalist mode of production means the domination of living labor by its alienated, dead products. As he put it in Volume 1 of *Capital*, "Capital is dead labour which, vampire-like, lives only by sucking living labour, and lives the more, the more labour it sucks" (Marx, 1977, p. 342). The workers' labor is transformed into an independent power, standing over and against them. In capital, the living is transformed into the dead and what is dead takes on power over what is living (Foster & Clark, 2009, p. 10; Fromm, 1973, p. 339, n. 14; Neocleous, 2003).

Capitalism also involves the domination of the living in a broader sense. Marx wrote in the *Economic and Philosophic Manuscripts* that alienated labor makes nature into "an alien world inimically opposed" to the worker (Marx, 1964, p. 111). Through alienated labor, human beings do not engage nature as a life-giving milieu with which their labor is interconnected. Rather, nature is constructed as a set of resources to be exploited. The aim of this exploitation is not the immediate satisfaction of human needs but, rather, the augmentation of capital as self-valorizing value. Marx wrote that as nature is appropriated through alienated labor, "it more and more ceases to be *means of life*" (Marx, 1964, p. 109, emphasis in original). I want to suggest that this alienation of nature and of life today has two aspects. One is the degradation of the life-supporting abundance of the natural world through extraction, exploitation, and waste, resulting in the mounting global ecological crisis (Foster, 1994; Speth, 2008, pp. 17–66). The other is the production of life that is interpenetrated with capital and, hence, takes the form of capitalized life or living capital (Rikowski, 2003; Yoxen, 1981).

The subsumption of life by capital parallels and is related to the subsumption of labor. Labor is formally subsumed under capital when it takes the form of commodified labor capacity, in other words, when it becomes *wage labor*. Labor comes under real subsumption when capital assumes direct control over the labor process, transforming working activity so that it takes on a specifically capitalist character. In numerous passages, Marx described how mechanization represents a transformation of labor such that the worker's life-activity is appropriated and subsumed by capital

in the form of technology. The machinery develops complexity and takes on a central power in the production process as the worker's activity is simplified and fragmented (Marx, 1973, p. 693; see also Bowring, 2003, pp. 103–104). Hence, according to Marx, “What was the living worker's activity becomes the activity of the machine” (Marx, 1973, p. 704).

The reification of labor as a commodity is experienced by the worker as estrangement from his living activity, as his work is regulated, standardized, and disciplined. What Harry Braverman (1974) described as the “degradation” of work accompanies and is a condition of the augmentation of the capacities of machinery in the productive process. Marx argued that, under capitalism, value is derived from “abstract human labour,” that is, labor as a general capacity abstracted from such concrete actions as weaving or tailoring (Marx, 1977, p. 150). It is also implied by Marx's theory of real subsumption that capital tends to reconstruct labor as an activity, so that differentiating qualities are increasingly lost. The specifically capitalist labor process is one in which work is simplified and rendered abstract in practice, as the organizing intelligence in the labor process passes from the worker to capital itself expressed in the system of machinery.

The tendency in Taylorism, automation, and later twentieth-century developments in computerization is toward the loss of differentiating qualities from work. Hence, the mid-twentieth century saw the rise of the “mass worker” whose working activity “meets Marx's definition of ‘abstract labour’ – labour which is independent of the particular concrete form it takes at any given time” (Bowring, 2004, p. 106; see also Hardt & Negri, 2000, p. 292).

Continuous with modern capitalism's tendency toward abstract labor is a tendency toward abstract life. This means the decontextualization, reification, and commodification of the productive and reproductive capacities of living things.² Sociologists William Boyd, W. Scott Prudham, and Rachel Schurman argue that an *analogy* can be drawn from Marx's concepts of the formal and real subsumption of *labor* to the formal and real subsumption of *nature*. Under formal subsumption, nature is transformed into a set of resources and commodified. But the “natural schedules of biological or geophysical (re)production,” the available natural stock of these resources, and their geographical location are confronted by the capitalist as exogenous brute facts (Boyd, Prudham, & Schurman, 2001, p. 563). This is the case in extractive industries such as mining and logging. In contrast, “The real subsumption of nature refers to systematic increases in or intensification of biological productivity” through inputs such as fertilizers and growth hormones or through the manipulation of the genetic program (Boyd et al., 2001, p. 564). Under real subsumption, capital imposes a specifically capitalist mode of (re)production, speeding up natural processes or altering them to increase reliability, predictability, efficiency, and control.

Boyd, Prudham, and Schurman are too cautious, however, in referring to the relationship between the real subsumption of labor and that of nature as merely *analogous*. These are not mere analogies but are actually historically and practically interrelated developments. Marx treated the organization of labor and the

organization of nature as interrelated aspects of the capitalist production process. Just as labor is transformed, through its combination and mechanization, nature is transformed as “gigantic natural forces [. . .] [are] pressed into the service of production” (Marx, 1977, p. 775). The pioneer of Marxist environmental critique, John Bellamy Foster, suggests a close *actual* relationship between the real subsumption of labor and nature as interconnected developments within monopoly capitalism. The scientization of production was closely related to the concentration of capital in oligopolistic enterprises. The application of science in the chemical and electrical engineering industries meant a new level of capital-intensiveness that gave advantage, through economies of scale, to large firms. Foster argues that the scientization of production under monopoly capitalism “was aimed at extending both the division of labor and the division of nature, and in the process both were transformed” (Foster, 1994, p. 110). The real subsumption of labor and nature both tended toward simplification and homogeneity: “complex, highly skilled labor was to be reduced to its simplest most interchangeable – and hence cost-efficient – parts. [. . .] As labor became more homogeneous, so did much of nature, which underwent a similar process of degradation” (Foster, 1994, p. 111).

Modern sciences of genetics and bioengineering have pioneered the control of life – for example, in the production of standardized organisms, such as particular varieties of mice or fruit fly, for use as experimental models (Kohler, 1994; Rader, 2004). Today, such scientific techniques are harnessed closely to capitalist production, so that the control of life through genetic engineering and biotechnology allows the intervention in reproductive processes so as to configure these for efficient commodity production. In this process, life is rendered abstract. Particular qualitative differences (for example, between species) are overcome as genes are moved around and spliced between organisms and as, in synthetic genomics, the disassembly of life into its most basic components facilitates the assembly of new forms of life as patented living commodities. Sociologist Finn Bowring argues that “modern biotechnology [. . .] allows human beings to disregard animals’ natural form of life.” At its most extreme, “its goal is to transform the natural world into a universe of functional bio-machines” (Bowring, 2003, pp. 134, 143).

As well as in genetic engineering and “synthetic biology,” abstract life is expressed in what John Johnston (2008) calls the “machinic life” of robotics and computational artificial life. While synthetic genomics attempts to create “programmable” biological organisms, bringing the logic of engineering into the biological realm, the fields of machinic life may be seen as an attempt to relocate the reproductive capacities of life in the inorganic domain of metallic robots and computers. In new fields such as bionanotechnology, we can see practical efforts to break down the boundaries between what practitioners refer to as “hardware,” “software,” and “wetware,” and indeed to merge the so-called hard artificial life of computing and robotics with the so-called wet artificial life of synthetic biology.

Robotics pioneer Rodney Brooks suggests that the melding of flesh and machine is pervasive in contemporary culture: “Researchers are placing chips in animal, and

sometimes human, flesh and letting neurons grow and connect to them. The direct neural interface between man and machine is starting to happen. At the same time, surgery is becoming more acceptable for all sorts of body modifications" (Brooks, 2002, p. x). As the robotics revolution becomes integrated with the biotechnology revolution, he argues, "Our machines will become much more like us, and we will become much more like our machines" (Brooks, 2002, p. 11).

In these discourses and accompanying practices, life is thereby abstracted not only from particular organisms and ecologies, but also from the organic altogether: life becomes instead a set of abstract functions that may be expressed in either animal or machine or in their combination. The constitution of abstract life tends toward the *conceptual* abstraction from qualitative differences between the organic and the non-organic and toward their *practical* reconstitution.

The technological convergence between the sciences of automation, information, and biological control, signaled by acronyms such as "GNR," suggests the convergence between abstract labor and abstract life. Such ideas are part of the discourse of capitalist techno-futurism, a way of promising continued progress and the continual reinvention of capital (Cooper, 2008). An advertisement for the Lexus automobile forecasts: "Someday nanotechnology will be used to turn plants into [automobile] components" (Lexus, "Hello Someday" advertising campaign, October 2009). The dream of total automation and the workerless factory, central to the techno-utopian fantasies of robotics and nanotechnology pioneers, combines with visions of the total control of the reproductive capacities of living organisms. Such techno-futurist visions are not idle fantasies but are pursued in the projects of universities, spin-out firms, and industrial research laboratories. What such visions and projects augur is the emancipation of capital from its dependencies on human and biological life exogenous to it through the appropriation of life for capital itself. "Thus all powers of labour" *and*, we should now add, *of life*, "are transposed into powers of capital" (Marx, 1973, p. 701).

A Dead Planet

We are currently undergoing what scientists dub the "sixth extinction," the sixth mass extinction event in the world's history – and the first one that is caused by human activity (Ananthaswamy, 2004; Eldredge, 1998; Leakey & Lewin, 1995). Plant and animal species are vanishing at 100 to 1,000 times the natural "background" extinction rate. In its 2007 survey of species, the International Union for the Conservation of Nature found that 39% of the species it surveyed were threatened with extinction: "one in three amphibians, one quarter of the world's pines and other coniferous trees, one in eight birds and one in four mammals" (Novack, 2008; see also Ananthaswamy, 2004; Severino & Seligmann, 2008). The Zoological Society of London (ZSL) reported in 2008 that the world's population of wildlife has fallen by between a quarter and a

third since 1970. Populations of marine species fell by 28% in just 10 years (1995 to 2005) and populations of ocean birds have fallen by 30% since the mid-1990s (“Wildlife Populations,” 2008). The editor of the ZSL report, scientist Jonathan Loh, described the decline as “completely unprecedented in terms of human history. You’d have to go back to the extinction of the dinosaurs to see a decline as rapid as this” (ZSL, 2008). This massive loss of species is caused by a combination of the destruction of natural habitat, overexploitation, pollution, the spread of invasive species, and, increasingly, the effects of climate change.

Ocean ecosystems are under severe pressure due to exploitation and pollution, leading to a dramatic decrease in the diversity and complexity of ocean life. According to marine ecologist Jeremy Jackson:

Synergistic effects of habitat destruction, overfishing, introduced species, warming, acidification, toxins, and massive runoff of nutrients are transforming once complex ecosystems like coral reefs and kelp forests into monotonous level bottoms, transforming clear and productive coastal seas into anoxic dead zones, and transforming complex food webs topped by big animals into simplified, microbially dominated ecosystems. (Jackson, 2008)

Overfishing has led to the plummeting of fish stocks. Descriptions from the preindustrial era portray an abundance of ocean life that is now hard for us to imagine. Callum Roberts, Professor of Marine Conservation at York University, remarks that, “We have come to accept the degraded condition of the sea as normal. People [. . .] dismiss as far-fetched tales of giant fish or seas bursting with life” (quoted in Vidal, 2008, p. 26). An article in *The Economist* notes that

the fish that once seemed an inexhaustible source of food are now almost everywhere in decline: 90% of large predatory fish (the big ones such as tuna, swordfish and sharks) have gone, according to some scientists. In estuaries and coastal waters, 85% of the large whales have disappeared, and nearly 60% of the small ones. Many of the smaller fish are also in decline. (Grimond, 2009, p. 3)

Effects of overfishing are compounded by global warming. Coral reefs are bleached and dying: “Perhaps only 5% of coral reefs can now be considered pristine, a quarter have been lost and all are vulnerable to global warming” (Grimond, 2009, p. 4). There are ever more algal blooms appearing in the oceans and ever more and ever larger “dead zones” caused by algal blooms, areas of ocean depleted of oxygen and therefore sea life. These had been known to occur as the result of fertilizer run-off from agriculture. They are now occurring more frequently, independently of fertilizer run-off, apparently from global warming causing shifting ocean currents to bring nutrients up from the depths to the surface, leading to growth of algae. In 2006, the UN Environment Program said that the number of such dead zones had grown by a third in the space of two years (Grimond, 2009, p. 4; Than, 2009; “UN: Ocean Dead Zones,” 2006). According to a Pulitzer Prize-winning *Los Angeles Times* story, the algal

blooms are “distress signals from an unhealthy ocean. Overfishing, destruction of wetlands, industrial pollution and climate change have made the seas inhospitable for fish and more advanced forms of life and freed the lowliest – algae and bacteria – to flourish” (Weiss & McFarling, 2006). The complex ocean ecosystem, once capable of sustaining abundant and diverse life, is being transformed into an eviscerated environment sustaining only simplified and less diverse organisms.

In recent years, there have been a number of both disturbing and poorly understood cases of the crashing of wildlife populations. Scientists do not fully understand what is causing the Colony Collapse Disorder affecting honeybee populations in the United States and Europe, but it seems to be the result of a “synergistic” combination of stresses such as chemical pollution, parasites, pathogens, and lack of food (MacKenzie, 2009; “Scientists Untangle,” 2009). It is similarly unclear what is behind the fungal infection known as “white nose syndrome” that is killing vast numbers of bats in North America (Kolbert, 2009, pp. 60–62). Along with factors such as disease and habitat destruction, chemical pollution is thought by scientists to be a contributor to the sharp decline of amphibian populations, with 32% of the world’s amphibian species now threatened (“Worldwide Amphibian Declines,” 2009). A recent study suggests that deformities found in increasing numbers of frogs in the United States are “caused by a synergism between parasitic infection and exposure to low levels of agricultural chemicals” (Hileman, 2002). Professor of Ecology Joseph M. Kiesecker speculates, in line with this, that chemical pollution may be “changing the environment in ways that increase disease prevalence” (quoted in Hileman, 2002; see also Collins & Crump, 2009, esp. pp. 8, 99–100, 101–104, 198–199).

Soil erosion is a silent crisis facing global agriculture. As environmental journalist Stephen Leahy puts it, “in the past 40 years alone, 30 percent of the planet’s arable land has become unproductive due to erosion, mainly in Asia and Africa. At current erosion rates, soils are being depleted faster than they are replenished” (Leahy, 2008; see also Sample, 2007). According to Lester Brown, director of the Earth Policy Institute research group, deforestation and overgrazing in Africa are contributing to dust storms that “are slowly draining the continent of its fertility and biological productivity” (quoted in Vidal, 2009).

Deforestation, in particular the destruction of the rainforests, is a major cause of biodiversity loss and a contributor to climate change and is caused by logging, clearance for agriculture, mining and industrial development, and dam projects (“Amazon Carbon Sink,” 2004; “Amazon Destruction,” 2005; Pearce, 2006). Deforestation of tropical forests and primary forests increased in the first five years after the millennium, compared with the 1990s (though the Brazilian government recently announced plans to reduce the rate of deforestation). According to the environmental news site Mongobay.com, “each day at least 80,000 acres (32,300 ha) of forest disappear from Earth” (“A World Imperiled,” ca. 2009; see also “70% Deforestation,” 2008).

Climate change caused by greenhouse gas emissions (and intensified by deforestation) adds to and compounds problems of the alteration and depletion of life-sustaining systems and the extinction of species (Pounds & Puschendorf, 2004;

Science Daily, 2007). Research by NASA scientist James Hansen reveals that the planet has undergone warming of 0.6°C (1.08°F) since 1970 and the 10 hottest years occurred between 1997 and 2008. This warming is due to accelerate, with devastating consequences. As Hansen puts it, these changes place the world in “imminent peril” (quoted in McKie, 2009). In 2004, a group of zoologists and biodiversity scientists wrote to *Nature* predicting “on the basis of mid-range climate-warming scenarios for 2050, that 15–37% of species in our sample of regions and taxa will be ‘committed to extinction’” (Thomas et al., 2004). In 2007, the Intergovernmental Panel on Climate Change warned that 20–30% of plant and animal species would be at increased risk of extinction if average global temperatures were to rise by 2.7 to 4.5 degrees Fahrenheit (Bethge, 2007). On January 28, 2009, Al Gore testified to the Senate Foreign Relations Committee that if carbon emissions were unchecked, global average temperatures could rise by 11 degrees Fahrenheit over the next century. With increased desertification and crop failure cutting food supplies, as well as the melting away of glaciers threatening water supplies for irrigation and drinking water, such a development would bring “a screeching halt to human civilisation and threaten the fabric of life everywhere on Earth” (quoted in Goldenberg, 2009).

Already, climate change is producing serious water shortages. According to the Working Group on Climate Change and Development, the melting of Andean glaciers “forces people to farm at higher altitudes to grow their crops, adding to deforestation, which in turn undermines water resources and leads to soil erosion and putting the survival of Andean cultures at risk” (quoted in Vidal, 2006). In 2008, the executive director of the UN Environment Program warned that climate change may lead to severe droughts and water shortages such that parts of the world may have to be abandoned by humans (Jowit, 2008). So the creation of oceanic dead zones is paralleled on land by desertification: complex life-sustaining ecosystems are replaced by simplified ecologies incapable of supporting human life.

The evisceration of ecosystems is connected with a more general process of homogenization. Biodiversity is lost, and wild species give way to domesticated monocultures of industrialized farming. The destruction of the wild accompanies and furthers the global expansion and dominance of a globalized corporate culture in which all differences are assimilated to a common commodity form. The loss of habitat for wild species is accompanied by the loss of diversity of human cultures. As journalist Terry Glavin points out, a corollary of the extinction of species is the destruction of indigenous peoples and the extinction of their cultures and languages (Glavin, 2006; Nettle & Romaine, 2000). The complexity both of nature and of human cultures is being diminished, giving way to monoculture. The environmental crisis manifests a powerful tendency toward *simplification* (Wessels, 2006).

We are seeing not only the extinction of wild species, but also a dramatic decline in the diversity of domesticated plants and animals. Glavin writes, “by the beginning of the twentieth century, about 4000 breeds of animals had been domesticated, but by the end of the century, 618 of those distinct breeds were extinct and another 475 were threatened with extinction” (Glavin, 2006, p. 219). It is estimated that the

diversity of major livestock breeds is diminishing at about 5% per year (Glavin, 2006, p. 219). There has also been a dramatic reduction in genetic diversity in all major food crops over the course of the twentieth century (Glavin, 2006, p. 214). What Pat Mooney, executive director of the Rural Advancement Foundation International, calls a “plague of sameness” attacking the world’s plants has accelerated with contemporary agrobusiness and biotechnology (quoted in Glavin, 2006, p. 214). The tendency toward sameness was exacerbated by the industrialization of agriculture promoted in the post-World War II “Green Revolution,” which increased and concentrated the corporate control of agriculture (Glavin, 2006, pp. 217–223).

Industrial agriculture imposes standardization and monoculture, abstracting the reproduction of plants and animals from the interconnected processes of natural ecosystems. Sociologist Barbara Adam describes how industrial agriculture abstracts not only from place, but also from time. Technoscientific and industrial techniques detach agriculture from the natural rhythms that traditionally linked the patterns of farming to those of the natural world:

Despite this inescapable tie of (almost all) life forms to the earth’s rhythmicity and seasonality, attempts are being made to transcend that context-bound temporal characteristic and incorporate agriculture more fully within the industrial way of doing things: improve productivity, efficiency and profitability by creating sheep that “produce” lambs twice a year, crops that grow in extended seasons, apples that keep for an extra couple of months. (Adam, 1998, p. 141)

A similar process of abstraction is indicated by the distinction drawn by biologists Richard Lewontin and Jean-Pierre Berlan between farming and agriculture: “Farming is producing wheat; agriculture is turning phosphates into bread” (quoted in Foster, 1994, p. 117).

Agriculture relies increasingly on industrial inputs of fertilizer, pesticides, and machinery. In many cases, industrialized agriculture involves the total abstraction of the organism from the environment. Foster gives the example of cattle “removed from pasture and raised in feedlots.” Under these industrial conditions, “their natural waste, rather than fertilizing the soil, becomes a serious form of pollution” (Foster, 1994, p. 122). Industrial raising and slaughter of animals exemplifies the linkages between the real subsumption of labor and the real subsumption of life. In the mechanized chicken processing plant, one can see the relationship between the standardization of nonhuman animals as commodities and the routinization and control of human labor (Horowitz, 2004, esp. pp. 228–229).

The intimate historical and material relationship between the real subsumption of labor and the real subsumption of life is also indicated by Barry Commoner’s 1976 analysis of the economic roots of the energy crisis of that decade. Commoner pointed out that the extreme energy dependence of our economic and social activities was a relatively recent phenomenon: “there have been sweeping changes in the technology of agricultural and industrial production in the last thirty years”

(Commoner, 1979, p. 211). New technologies integrated into mass production after World War II massively increased the environmental impacts of the modern economy. The economy became more dependent on oil with highway building and increased use of automobiles and trucks for transportation. Petrochemical products became much more widely used in industry, agriculture, and in consumer products. The vast quantities of non-biodegradable, and often toxic, synthetic products produced and used in the postwar period marked this, Commoner argued, as the “Synthetics Age” (Commoner, 1979, p. 187). The combined capital-intensiveness and energy-intensiveness of the new industrial system was driven by attempts to integrate science into the production process so as to subsume both nature and labor. The new highly energy-dependent petrochemical agriculture was aimed at overcoming the barriers to profitability posed by natural growth cycles and local ecological conditions: harnessing nature to industrial patterns and products. Industry itself was becoming more capital- and energy-intensive in the ongoing quest to replace labor with automatic machinery. Commoner argues that the overriding obsession with increasing the productivity of labor led to a capital-intensive and energy-intensive apparatus of production, one which is highly wasteful and inefficient in its use of natural resources (Commoner, 1979, p. 212). Commoner points to the relationship between the real subsumption of labor via mechanization and the degradation of the environment.

Drawing on Commoner’s analysis, Foster argues that the post-World War II system of mass production and industrial agriculture is “counter-ecological.” The system is predicated on the *denial* of the ecological principle that “everything is connected to everything else” (Foster, 1994, pp. 118, 120). The standardized, simplified ecosystems of industrial agriculture are expressions of the way in which industrial agriculture binds life to the abstract value of money. In contrast to the interconnectedness of living things within natural ecosystems, in capitalist agriculture, as Foster puts it, “the only lasting connection between things is the cash nexus” (Foster, 1994, pp. 120–121).

We are frequently left with the remnants of formerly vibrant ecosystems: parks and zoos rather than genuine wilderness and wildlife. As wilderness is eliminated through deforestation, as the fabrics of ecosystems are ripped apart, and as biodiversity of both wild and domesticated nature is lost, species are preserved in a “living dead” form in zoos and national parks. Glavin (2006) writes that “living dead” is “a term biologists have begun to use to describe those species that are not expected to escape extinction without significant human intervention, such as captive breeding. Among the world’s endangered mammals, birds, and reptiles, already 1500 species are expected to be wholly dependent upon captive breeding by 2050” (pp. 20–21). The surviving members of these species live an abstracted existence in parks or zoos; they become specimens. As Glavin puts it, “they will not be ‘wild’ animals at all. They will be functions of artificial selection. They will live on in zoos, and perhaps some large parks [. . .] They will live in a simulacrum of the real world” (Glavin, 2006, pp. 24–25). The boundary between the natural and artificial is broken down as

the survival of these specimens comes to depend on interventionist programs of captive breeding. Such programs are promoted in terms of the pervasive ideology of techno-salvationism: "The alchemies of cryogenics, transgenetic manipulation, and the emerging biotechnologies that zookeepers are developing raise the very real possibility that many of the 'living dead' species of the world will never become extinct, at least not in the way that geneticists or taxonomists use the term" (Glavin, 2006, p. 38). In the United States and Britain, zoos and natural history museums are preserving genetic information on endangered species as "frozen arks" (Glavin, 2006, pp. 38–39; Harmon, 2009). As Glavin points out, given the destructive trajectory of modern societies, the notion that such projects constitute an "ark" and that there will at some point in the future be wild habitats into which these species can be restored seems "utopian." Instead, the most that such projects seem to promise is merely the indefinite maintenance of the "living dead" status of such species (p. 39).

Species are extracted from decimated ecosystems and preserved as specimens in zoos, and their sperm, embryos, tissue, and DNA are preserved. Already, the reproduction of these endangered species is increasingly indebted to techniques such as artificial insemination. Glavin writes, "Semen is being extracted from anesthetized tigers and stored away in frozen test tubes. The fertilized embryos of endangered gaurs are being implanted in Holstein cows. Horses are giving birth to zebras" (p. 39). So alongside the abstract existence of these species as "specimens," there is a further abstraction at work, accomplished by the new capabilities of genetic engineering. These species are preserved as abstract life. The preservationist project becomes linked to the technological control of abstract life in which qualitative differences between organisms and species are overcome. As Glavin puts it, "it is about the bleeding away of differences in the living world, and of differences between captivity and freedom, between the real and the fabricated" (pp. 30–31).

Artificial Life

Animal specimens are being abstracted, for their own protection, from ecosystems that are being destroyed. At the same time, genetic engineering is producing new animal strains which themselves are seen to represent risks to natural ecosystems and which therefore must be segregated. An example is the controversial transgenic AquaAdvantage salmon, developed by the company AquaBounty to be faster-growing than natural varieties of salmon currently used in aquaculture. Transgenic salmon are controversial due to worries about the potential for their escape from aquaculture nets into the wild and the possibly disastrous effects of their breeding with wild salmon. The production of transgenic salmon would be continuous with the dynamics of capitalist industrialized agriculture whereby natural processes are overcome in the cause of the enhancement of productivity; reproductive capacities of life are mobilized, but reconfigured to fit with capitalist dynamics (Bowring, 2003; Kelso,

2003, p. 93). This poses the problem of the relationship between this manufactured life-form and the broader natural environment. The risks are unknown: the existence of such life in the natural environment takes the form of a “real-world experiment” (Levidow & Carr, 2007). Risk is contained by the sequestration of the new organism from the ecosystem. The AquaAdvantage salmon is designed to be sterile, this sterility protecting not only the intellectual property of the biotech corporation but also the environment (Kelso, 2003, p. 89). Yet, the sterility of all individuals in a population may not be guaranteed so there is also the problem of the containment of the creatures from the environment. For the protection of the natural environment, either by sterility or by spatial segregation in “escape-proof facilities,” these creatures may have to be kept in abstraction from the ecosystem (Kelso, 2003, p. 101).

“Life” is today radically abstracted, re-situated, and reconfigured. The term “artificial life” is used with broad connotations in this chapter to denote the manifold ways in which modern technosciences, including genetic engineering, computing, robotics, and nanotechnology, are technologizing biological life and creating new forms of autonomous, self-replicating, and, hence, “lifelike” machines. But “artificial life” is also a term of art, and one of the most radical challenges to existing conceptual and ontological barriers between life and technology has come from the new technoscientific field that takes the name of “Artificial Life” (hereafter, AL). Thomas Ray, a pioneer of the field, defines its goal as “understanding biology by constructing biological phenomena out of artificial components, rather than breaking natural life forms down into their component parts. It is the synthetic rather than the reductionist approach” (Ray, 1995, p. 179). The umbrella incorporates hardware (robotics, nanotechnology), software (“replicating and evolving computer programs”), and wetware (“replicating and evolving organic molecules”) (Ray, 1995, pp. 179–180). AL seems, however, to be mainly associated with the “software” aspect in which Ray himself specializes and which is associated with the complexity and computational sciences of the Santa Fe Institute in the United States (Helmreich, 1998). The thrust of the project is the computer simulation of the self-organizing, replicating, and reproductive capacities of living things and ecological systems. These simulations inevitably raise the problem of the relationship between the simulated and the real: the philosophical question underlying much of the interest in AL is whether this “life on screen” is not merely “like” a living system but is an alternative *instance* of life (see Turkle, 1995, pp. 154–158).

Although Ray emphasizes that AL is synthetic, not reductionist, it nevertheless follows the logic of abstract life. Ray writes:

Our concepts of biology, evolution, and complexity are constrained by having observed only a single instance of life, life on earth. A truly comparative biology is needed to extend these concepts. Because we cannot observe life on other planets, we are left with the alternative of creating Artificial Life forms on earth. I will discuss the approach of inoculating evolution by natural selection into the medium of the digital computer. (p. 179)

Stefan Helmreich writes that AL may be seen as the consolidation of theoretical biology, artificial intelligence, and robotics. But he argues that the project derives much of its character from theoretical physics: "This shapes [. . .] its claims to be a biology that will be true anywhere in the universe, just as physics is true everywhere in the universe" (Helmreich, 1998, p. 47). AL operates with a conception of life that is abstracted from any given existence, form, or environment. From the initial abstract, universalistic, theoretical physics-influenced concept of life there follows the thought that life could evolve beyond the merely incidental biological forms of plants, animals, and micro-organisms.

Techno-futurist literature often posits a movement from biological to technological evolution. Carnegie Mellon University artificial intelligence researcher Hans Moravec is a key proponent of a kind of cosmic transhumanism in which living intelligence evolves beyond the organic to inhabit machines, and ultimately to inhabit the universe itself, as intelligence takes on new manifestations in post-terrestrial, post-Darwinian life. "We are," he says, "in the process of inspiring the dead matter around us. It will soon be our honor to welcome some of it to the land of the living" (Moravec, 1999, p. 111). Moravec fantasizes about the diversity of this posthuman and post-terrestrial intelligent life, evolving over the next millennium from his own and his colleagues' attempts to instill intelligence in non-organic matter. As "ex-human" life, derived from these experiments, evolves to inhabit outer space, this new extra-terrestrial ecology will become "much more diverse than Earth's biosphere, shaped by discoveries and inventions yet to be made and thus hard to conceive" (Moravec, 1999, pp. 146–147).

The prediction of a new diversity of artificial life is put forward also by Rodney Brooks, the director of the MIT Artificial Intelligence Laboratory. He foresees a "Cambrian explosion" of robotic life, a new complexity and diversity in artificial intelligence and robotics reminiscent of the rapid proliferation of complex biological organisms about 530 million years ago. Indeed, Brooks saw his laboratory's creation of "Genghis," an insectlike robot, in which the interaction of simple components yielded complex behavior that gave the appearance of intentionality, as the beginning of his laboratory's own "Cambrian explosion" (Brooks, 2002, p. 51).

Brooks insists that the robots that he is producing, able to act somewhat autonomously in unstructured environments, "are not just robots. They are artificial creatures" (Brooks, 2002, p. 11). Brooks's vision is shared by scientists working on the Symbion Project at the University of the West of England (UWE) in Bristol. The project involves the construction of motorized robots, each roughly the size of a sugar cube, which are able to communicate with one another and to "assemble themselves into much larger machines to carry out specific tasks when required" (Sample, 2008). According to Alan Winfield of UWE, these robots will "not only [. . .] cooperate, they'll self-assemble and self-organise into artificial organisms" (quoted in Sample, 2008). Like Brooks's insectlike robots, these are also modeled on an ant or termite colony, each organism relatively simple but together forming swarms that can manifest adaptive behavior.

There is a growing interest in designing robotics to mimic the natural world. Researchers at Tufts University are attempting to develop a robot that mimics the motion of caterpillars. A *New York Times* article reports:

In trying to reproduce the caterpillar, the Tufts researchers are taking part in one of the biggest trends in robotics and locomotion studies, which are increasingly taking inspiration from the world of biology. Joseph Ayers of Northeastern University in Boston has created an artificial lobster. Ian Walker of Clemson University in South Carolina has a robotic arm that draws its inspiration from the elephant's trunk and the octopus's arm. There are robotic salamanders, snakes, cockroaches, fish and geckos. (Schwartz, 2007)

Such robots frequently have military applications. The MIT-linked defense robotics firm Boston Dynamics produces robots that mimic animal motion, such as the four-legged "Big Dog" that can carry supplies over rugged terrain. A collaboration between University of Pennsylvania, Carnegie Mellon, Stanford, UC Berkeley, Lewis and Clark University, and Boston Dynamics has produced the "bioinspired" RiSE robot, capable of climbing vertical walls, a project that obviously has surveillance and military applications.³ iRobot, the private firm founded by Brooks, has also become a major manufacturer of robots for war (Singer, 2009, p. 111).

The development of animal-mimicking robots is paralleled by the technologization of animals. There is a trend, particularly in military and security research, to use animals as instruments. Scientists at Los Alamos have used Pavlovian conditioning to train bees to detect explosives. A newspaper article on this development features pictures of bees restrained in "specially designed harnesses" at the laboratory ("Bomb Squad," 2006) (see Figure 26.1). This denaturing of the animal, as it is placed under laboratory controls and divorced and deprogrammed from its natural behavior, aims at turning the animal into a technological tool. The hope is to integrate the bee into a device. The research scientist leading the project claims that "the bees could be carried in hand-held detectors the size of a shoe box, and could be used to sniff out explosives in airports, roadside security checks, or even placed in robot bomb disposal equipment" ("Scientists Train Bees," 2006).

Genetic engineering aims at an even more fundamental technologization and control of living creatures. The production of transgenic animals collapses barriers between life and technology and between species, but also merges what were previously distinct sectors of production: agriculture, pharmaceuticals, and the industrial production of materials. In February 2009, the US Food and Drug Administration (FDA) approved the safety of ATryn, an intravenous anti-clotting drug produced in the milk of genetically engineered goats (Lite, 2009). The Canadian firm Nexia Biotechnologies has created a goat that produces spider silk protein in its milk. As the company's CEO puts it, the genetically altered goats are "cheap factories" for the company's product, an ultra-strong material that they have dubbed "BioSteel" (quoted in Barad, 2007, p. 469 n. 26; "GM Goat Spins," 2000).

The technologization of animal life is carried forward by the new potential for the standardization of animals through cloning. Cloning represents an extension of the simplification of nature that one finds in agricultural monoculture, and the key application of cloning is in agriculture. The *New Scientist* notes that “cloning [. . .] offers a much more precise way of making genetically engineered animals. Traditionally, transgenic animals were made by injecting gene copies into a new embryo – an inefficient and chaotic process. Genes can land anywhere in the genome, disrupting other genes. Now researchers can insert DNA at a precise position into a single adult cell, and then clone it to create the desired animals” (Aldhous & Coghlan, 2006, p. 10). So cloning is a radical extension of engineering control over life and therefore of the capitalist subsumption of life, rendering life compatible with industrial norms of precision, standardization, and regularity.

Synthetic biology represents a still more radical development beyond genetic engineering. In a paper published in *Science* in early 2008, the J. Craig Venter Institute announced that its scientists had created a synthetic chromosome, synthesizing from laboratory chemicals the genome of the bacterium *Mycoplasma genitalium* (Jha, 2008; “Patent Pending,” 2007). This synthesis of DNA was a step toward Venter’s “ultimate goal of inserting the synthetic chromosome into a cell and booting it up

to create the first synthetic organism” (Synthetic Genomics, 2008). In 2010, Venter confirmed that his team had accomplished this next step, thereby making a “synthetic cell” (Robbins, 2010).

Computing imagery (such as “booting it up”) signifies the technologization of the organism and the ambition toward predictability and control (Hedgecoe, 1999, esp. pp. 217–218). William Boyd argues that there is an affinity between the conceptual modes through which biological technosciences approach life and the capitalist dynamics involved in the manipulation of life: scientific reductionism facilitates commodification. He argues that “the metaphor of life as code [. . .] has come to provide much of the foundation for efforts to ‘improve’ biological systems by intervening directly in the genetic program itself. Codes [. . .] can be cracked, programmed, and reprogrammed” (Boyd, 2003, p. 31). Nobel laureate Hamilton Smith, who led the scientific team at the J. Craig Venter Institute, likened the production of the artificial genome to finishing the operating system of a computer: “By itself, it doesn’t do anything, but when you install it on a computer, then you have a working computer system. It’s the same with the genome: the genome is the operating system for a cell and the cytoplasm is the hardware that’s required to run that genome” (quoted in Jha, 2008). The understanding of life in terms of hardware and software is bound up with the practical goal of the computer-assisted design of life: Venter called his new cell “the first self-replicating species that we have on the planet whose parent is a computer” (quoted in Robbins, 2010, p. 1).

Synthetic biology follows an engineering paradigm and there are striking similarities with Taylorism. Just as Taylorism involves the initial analysis of the worker’s living activity, the analytical breaking down of that activity into its constituent parts, and the re-engineering of the work process, similarly synthetic biology involves the breaking down of the complexity of life into relatively simple components with the aim of rebuilding these components. Like capitalist mass production, synthetic biology operates via the assembly of standardized or replaceable parts. A key tool of synthetic biology is known as the “BioBrick,” which consists of fragments of DNA. An article in the popular science magazine *BBC Focus* explains,

Scientists can clip DNA segments from nature, or they can order them. [University of California scientist Chris] Voigt prefers to order them, sending instructions listing what DNA he wants to a company, which will then synthesise the strings of genetic material for him. In this case, the company copies segments of existing DNA using a polymer chain reaction (PCR) machine and puts them together in the required sequence. Alternatively, researchers can buy ready-made parts, known as BioBricks. The synthesised parts are made in a similar way, but researchers choose what they want from the BioBrick library. The parts will arrive suspended in a liquid and are then added to bacteria cells, such as *E. coli*. The bacteria is zapped with electricity to create pores in the cell walls, a technique which allows the DNA to filter inside. (O’Connell, 2006, p. 49)

The BBC article emphasizes that this use of standardized parts reflects an engineering orientation and points out that “a number of this new breed of biologists have

come from an engineering rather than a life sciences background” (O’Connell, 2006, pp. 49–50).

The production of abstract life means intervention aimed at overcoming the complexities and interdependencies of the natural world, as the following quote in the BBC article makes clear:

Professor Tom Knight, senior research scientist at MIT, draws a parallel with a joke often told to illustrate the differences between scientists and engineers. A scientist goes into her lab and carries out an experiment. When she gets the result, she discovers that the system she is studying is twice as complicated as she thought. “Great,” she thinks to herself, “I get to write a paper on that.” An engineer goes into her lab and carries out the same experiment. But this time, when the results come back and she sees that the system is twice as complicated as she’d predicted, she says to herself: “Now how do I get rid of that?” “I’m firmly in the ‘how do I get rid of that’ category!” says Knight. (O’Connell, 2006, p. 50)

Synthetic biology is an assault on complexity not only analytically, but also in practice, as it seeks to package nature into standardized components in aid of producing standardized engineered-but-living products.

Drew Endy, another MIT scientist working in synthetic biology, explains that the goal is to build predictability into biological processes: “We can probably engineer biology in such a way to produce components that are insulated from one another, that are designed to be easy to put together and then behave in ways that you expect” (quoted in Jha, 2005). As science journalist Alok Jha put it, “if biology is to truly turn into a technology, engineers need to develop standard biological components that they can simply plug into their application – something available in all other forms of engineering” (Jha, 2005). *The Economist*, which has published a number of cautiously optimistic articles about this new technoscientific field, notes that “Synthetic biologists plan to [. . .] industrialise the process in a way that will let people order biological parts as routinely as they order electrical components. If this vision is realised (and there is still a long way to go) biotechnology will become a true branch of engineering” (“Playing Demigods,” 2006).

Synthetic biology operates with abstract life – life broken down into components that can be treated as engineering tools. This abstraction is also abstraction from ecosystems and geography: the appropriation of the productive capacities of nature and their re-situation in a technological/industrial setting. In this way, the obstacles posed for capitalist production by natural scarcities, timescales, and geographies may be overcome. *Financial Times* journalist Clive Cookson writes, “within a decade some researchers believe that bacteria, for example, could be designed that would mass-produce drugs that currently have to be painstakingly harvested from rare plants” (Cookson, 2006).

Scientific reductionism and technological standardization are linked together in a process of the commodification of the living. As Nikolas Rose has written with regard to the development of the “molecular” approach to biomedicine:

Molecularization strips tissues, proteins, molecules and drugs of their specific affinities – to a disease, to an organ, to an individual, to a species. It confers a new mobility on the elements of life. They can be de-localized – moved from place to place, from organism to organism, from disease to disease, from person to person. (Rose, 2007, pp. 6–7)

These processes of reduction and manipulation are linked to what Rose calls “a new political economy of life in which [. . .] biopolitics has become bioeconomics” (Rose, 2007, p. 17). Epistemological reduction of the living to the level of the molecule combines with an engineering ethos that aims toward efficiently reordering life for the purpose of making it optimally productive.

The engineering paradigm in biology is merging with nanotechnology as a project of technologizing life and animating technology. Bionanotechnology is predicated on the notion that DNA molecules, proteins, and enzymes are already “machines” or “self-assemblers” found in nature, which can themselves manipulate matter at the nanoscale. The UK Biotechnology and Biological Sciences Research Council (BBSRC) defines bionanotechnology as

a multidisciplinary area that sits at the interface between engineering, biological and the physical sciences [. . .] The range of topics within bionanotechnology is broad and includes examples in which biological components may be used to facilitate new technologies (e.g. the reconstruction of biomolecular systems as machines or motors), as well as those in which new technologies are used in the study of biological systems. (BBSRC, ca. 2009)

The aim is to harness natural processes occurring at the nanoscale for a variety of applications from medicine to “molecular computing” to the manufacturing of materials. The linking of biotechnology with nanotechnology is associated with hopes of unifying biology with industry, harnessing natural reproduction to the production of medical and industrial technologies and consumer goods.

Although bionanotechnology is in its infancy and nowhere near the production of industrial-scale quantities of materials (Jones, 2004, p. 125), there are hopes for the possibility of scaling up. New York University chemist Nadrian Seeman has pioneered attempts to harness the self-assembly of DNA molecules to make complex self-assembled structures, leading ultimately to the ability to manufacture fibers or electronic devices. An article in the *Christian Science Monitor* describes him as the “Henry Ford” of nanotechnology, for his attempts to develop the production of molecular machines to industrial levels of efficiency and mass production. According to the article,

Nadrian Seeman sees a future filled with extremely small factory workers [. . .] He and a Chinese team at Nanjing University have built a nanoscale factory worker. The tiny machine is made of DNA, the molecule that governs the way cells make proteins [. . .] Seeman “programs” his tiny machine by stringing the right combinations of DNA – much in the way computer engineers use binary code [. . .] [He can] arrange pieces and form specific molecules with some precision – similar to the way a robotic automobile factory can be told what kind of car to make. (Emspak, 2009)

Commenting on the potential feasibility of Seeman's vision of molecular mass manufacture, British nanotechnology scientist Richard Jones notes that

molecular biology is being quickly industrialised; now adverts in the journal *Nature* compete to offer custom synthesis of DNA for as little as 80p per base. You simply send them the sequence you want and the money, and a couple of weeks later a little trace of DNA comes back. At the laboratory level, we have at least one demonstration that we can use the full power of self-assembly to make, not a single soft machine, but billions of them all at once. (Jones, 2004, p. 125)

The potential applications for bionanotechnology techniques are already entering into the imagination of new avenues for business (as in the Lexus advertisement quoted earlier). Cookson writes in the *Financial Times*: "The fusion of nanotechnology and biology may also allow us to grow products such as solar collectors and liquid crystal displays from living material" (Cookson, 2006).

A key feature of techno-futurist discourse is the image of the displacement of the factory and thereby the emancipation of production from its dependence on potentially antagonistic human labor. Seeman's "extremely small factory workers" signify an escape from dependence on human labor by harnessing the fundamentals of life. In nanotechnology guru Eric Drexler's visions of the future, the workers are self-assembling nanobots or "molecular assemblers" (Drexler, 1986, pp. 14, 54–58; Kurzweil, 2005, pp. 228–230). Ray Kurzweil draws on these ideas in a way that exemplifies how nanotechnology visions express the desire to meld production with life. In the idea of self-assembly, the productive apparatus of capitalism is imbued with life: "Self-assembly allows improperly formed components to be discarded automatically and makes it possible for the potentially trillions of circuit components to organize themselves, rather than be painstakingly assembled in a top-down process. It would enable large-scale circuits to be created in test-tubes rather than in multibillion-dollar factories" (Kurzweil, 2005, p. 115).

At the same time as life is reified, transformed into a mechanism or object, capital is strangely imbued with lifelike qualities. Drexler explicitly puts forward nanotechnology as a project which liberates capital from the productive and reproductive powers of both labor and nature, instead vesting those powers in technology and, hence, in capital itself. In *Engines of Creation*, Drexler writes:

Assembler-based systems, if properly programmed, will themselves *be* productive capital. Together with larger robotic machines, they will be able to build virtually anything, including copies of themselves. Since this self-replicating capital will be able to double many times per day, only demand and available resources will limit its quantity. Capital as such need cost virtually nothing. (Drexler, 1986, p. 94, emphasis in original)

Nanotechnology as "self-replicating capital" represents the emancipation of capital from contradictions and limits. Nanotechnology is the material realization of the ideal of productive capital, or, in Marx's terms, of capital as "self-valorizing value."

Melinda Cooper argues that the combination of economic crisis and a growing recognition of ecological limits, expressed most influentially in the Club of Rome's *Limits to Growth* report of 1972, was the impetus toward the development of the bioeconomy. The promotion of commercial biomedicine and bioengineering was, Cooper argues, in opposition to the tropes of stagnation and limits that pervaded the political economy and culture of the 1970s. Biotechnology, since highly dependent on venture capital, was economically linked to the financialization of the economy, the expansion of debt, and the uncoupling of the financial sector from the "real economy" (see also Rajan, 2006). It was a focal point for fantasies of the dematerialization of capitalism and the overcoming of all limits. These futures were founded on the assumption that "while industrial machines are subject to the laws of depletion and diminishing returns, life at its most 'lifelike' obeys a law of self-organization and increasing complexity. Where industrial production depends on the finite reserves available on planet earth, *life, like contemporary debt production, needs to be understood as a process of continuous autopoiesis, a self-engendering of life from life, without conceivable beginning or end*" (Cooper, 2008, p. 38, emphasis in original). Biotechnology was linked to the promise of self-reproducing capital and never-ending growth.

During the financial crisis of 2008, the surge of speculative money into commodities (combined with other factors including the taking over of agriculture by biofuel crops) led to a spike in food prices (Blas & Dinmore, 2008; Minder, 2008; Watts, 2009). At the height of the crisis, techno-salvationism reared its head, with genetic modification and other technoscientific innovations put forward as the solution to food scarcity. As food prices surged, the *Financial Times* called for a "second 'green revolution,'" arguing for new investment in raising agricultural productivity through advanced technology (Blas, 2008). The chairman of Nestlé took the opportunity of high commodity prices to make the case for overcoming European resistance to agricultural biotechnology: "You cannot today feed the world without genetically modified organisms" (quoted in Minder, Bounds, & Wiggins, 2008). As the world appeared headed for 1970s-style stagflation, Jeffrey Sachs asserted that new technologies offered a way out of both the food crisis and the broader economic crisis. Sachs argued for massive investment in sustainable technologies such as solar power, electricity storage and transmission, hybrid engines, carbon capture, cellulose-based ethanol, "safe nuclear power," new drought-resistant crop varieties, and new irrigation techniques that "can help impoverished farmers move from one subsistence crop to several high-value crops year round" (Sachs, 2008, p. 31). He opined that "countless other technologies on the horizon can reconcile a world of growing energy demands with increasingly scarce fossil fuels and rising threats of human-made climate change" (Sachs, 2008, p. 31). This new techno-salvationism offers to overcome the problems generated by past development and by earlier failed technological fixes. Climate change has exacerbated the depletion of world food stocks. But the legacy of the Green Revolution has also added to the problem, since it led to the development of agriculture that was highly dependent on energy and petrochemical inputs and water. The new "green revolution" means using biotechnology, including genetic

modification, to try to increase yields in spite of shortages of water and the growing cost of energy and petrochemical inputs (Beattie, 2008). Techno-enthusiasts become more insistent about the “imperative” for such technological fixes in proportion with the irrational, crisis-ridden nature of the prevailing economic system and its destructive relationship to the natural world (Vidal & Lawrence, 2010).

As the world’s politicians appear paralyzed in the face of global warming, techno-salvationism is rampant in this area. The Bush administration backed a range of technological fixes to the crisis, including “giant mirrors in space or reflective dust pumped into the atmosphere” (Adam, 2007; see also Broad, 2006; Etc. Group, 2007). Private corporations are seeking to profit from developing “geoengineering” solutions to climate change. Proposals have included spreading iron filings on the ocean surface to encourage plankton and sequester carbon dioxide (Etc. Group, 2007). There have been protests against an Indian and German expedition to the Antarctic to engage in experimentation involving the spreading of 20 tons of iron sulphate over a 300 sq km area in the Southern Ocean (Bhattacharya, 2009).

The environmental imbalance produced by carbon pollution creates a potentially lucrative demand for technoscientific products and expertise, and there are companies waiting to take advantage of such opportunities. Modern industrial civilization is doing away with the relatively stable and benign climate that has existed for 10,000 years since the last Ice Age. As the environmental journalist Fred Pearce puts it:

It is arguable that this rather benign world has been the main reason why our species was able to leave the caves and create the urban, industrial civilisation we enjoy today. Our complex society rests on our being able to plant crops and build cities, knowing that the rains will come and the cities will not be flooded by incoming tides. When that certainty fails [. . .] even the most sophisticated society is brought to its knees. But there is now a growing fear among scientists that, thanks to man-made climate change, we are about to return to a world of climactic turbulence, where tipping points are constantly crossed. (Pearce, 2006)

The life-sustaining environment that was a taken-for-granted common good can no longer be taken for granted and the maintenance of equilibrium in the atmosphere and ecosystem becomes potentially an artificial technological accomplishment. As our life on Earth becomes increasingly precarious, it becomes also increasingly artificial.

Even the problem of algal blooms in the oceans, caused by pollution and climate change, has become a focus for techno-salvationist hopes. The problem was highlighted when 32% of the 50 sq km area off the coast of Qingdao, devoted to Olympic sailing during the Beijing Olympics, was covered in algae. However, as well as raising awareness about the danger to ocean life caused by the industrial transformation of the environment, the algae also led to technovisionary speculation about the possibility of new biofuels. A *Financial Times* article noted: “But the crazy growth rates of algae under favourable conditions – doubling their mass every day or two – is one reason why they are seen as an attractive future prospect by the biofuels industry” (Cookson, 2008). An economic system that requires “crazy growth rates” finds a

match in an equally virulent and invasive species. And not content with existent green algae, bioscientists are seeking to engineer new varieties that may be more efficiently harnessed to capitalism's energy requirements: algae for biofuels is one of the potential applications that Craig Venter promises for synthetic life ("Craig's Twist," 2009).

The notion of a technological fix to environmental problems is also dear to the hearts of nano-visionaries. Drexler's nanotechnology manifesto, *Engines of Creation*, contains a chapter on "The Limits to Growth" that presents the nanosphere as holding the solution to problems of resource limits: "When we develop pollution-free nanomachines to gather solar energy and resources, Earth will be able to support a civilization far larger and wealthier than any yet seen [. . .] The potential of Earth makes the resources we now use seem insignificant by comparison" (Drexler, 1986, p. 162).⁴ Historian W. Patrick McCray argues that the techno-futurist thought of Eric Drexler and Ray Kurzweil was developed in reaction against the 1970s discourse of "limits to growth." In opposition to the image of Earth as a closed system, in which resources were being rapidly depleted, and the law of entropy applied, techno-futurists like Drexler looked to the infinities of outer space. Before transferring these fantasies of superseding limits into the realm of nanotechnology, Drexler was an enthusiast for space colonies (McCray, 2009; see also Drexler, 1986, p. 165). Access to resources beyond Earth remains central to Drexler's vision: "Yet Earth is but a speck [. . .] The resources of the solar system are truly vast, making the resources of Earth seem insignificant by comparison" (Drexler, 1986, p. 162). Similar extra-terrestrial fantasies are found in the writings of techno-visionaries such as Kurzweil and Moravec.

In Moravec, techno-futurist fantasies of artificial intelligence extending out beyond Earth into the universe combine with a romantic-primitivist critique of industrialism. Moravec's narrative begins with a loss of Eden and develops toward technological salvation. "A thousand centuries ago," he tells us, "the world was fully automated. Our ancestors were supported by the maintenance-free, self-operating machinery called Nature. But, in an Adamic bargain predating Faust, they meddled with the mechanism. By tilling and planting, they magnified the machinery's productivity but trapped themselves in a routine of heavy, unpleasant labor" (Moravec, 1999, p. 127). From agriculture developed urban civilization and modern industrial society. Unchanged biologically from our Stone Age ancestors, we are today born into a highly technologized, unnatural environment. There is a mismatch between the human organism and the industrial urban environment that "induces alienation in the midst of unprecedented physical plenty" (Moravec, 1999, p. 7). Since Moravec conceives of alienation in biological and essentialist terms, he can suggest that the problem is destined to be overcome by transcending and eliminating the biological human organism. "Technological evolution" will again restore us to our natural state of idleness as machines take over work, and "intelligence" will take flight from our unwieldy bodies to inhabit realms beyond Earth itself (Moravec, 1999, p. 9).

Kurzweil's fantasy of "the Singularity," similarly to Moravec, denies limits by imaginatively escaping from the constraints of Earth as the relevant environment.

In Kurzweil, the rejection of spatial limits (of Earth) and of temporal limits (via radical life-extension) is achieved ultimately through decorporealization. When minds can be uploaded as information to computational hardware, then

at that point the longevity of one's mind file will not depend on the continued viability of any particular hardware medium (for example, the survival of a biological body and brain). Ultimately, software-based humans [. . .] will live out on the Web, projecting bodies whenever they need or want them, including virtual bodies in diverse realms of virtual reality [. . .] and physical bodies comprising nanobot swarms and other forms of nanotechnology. (Kurzweil, 2005, p. 325)

Following abstract labor and abstract life, these fantasies involve a further abstraction: human existence is decorporealized and abstracted as "intelligence" and therefore delinked from its material ecological basis. Kurzweil's fantasy of endless growth deals with the problem of ecological limits just by denying the salience of ecology, seeking what he calls "transcendence" (Kurzweil, 2005, p. 388) in a decorporealized, informatic consciousness. But the fantasy of transcendence arrives at a state of incorporeal oneness with the universe that seems to be close to religious notions of the afterlife (Geraci, 2008). This artificial life of uploaded, incorporeal intelligence seems to be a form of death.

Conclusion

Artificial life and a dead planet are twin expressions of a world built on the basis of alienated labor. The alienation of one's own living activity produces an alienated relationship with the broader world of the living. The degradation of labor is implicated in the degradation of life. The imposition of capital's framework of value devalues the particularities and qualitative potentiality of the individual human being (Mészáros, 2008, p. 47). The broader living world of nature is also deprived of value, as that which cannot be rendered in cash terms no longer *has* value; hence, much of the Earth becomes a sink for pollution and other "externalities" of capitalist production. The standardization and disciplining of human productive activity are accompanied by the standardization and control of the reproductive processes of natural organisms. The living is reified, then, *symbolically* in terms of the way in which it is valued – quality being reduced to quantity – and *practically*, as both human activity and nature more broadly are degraded, standardized, and routinized, becoming increasingly *thing-like*.

As Philip K. Dick perceived, the reification of the living is accompanied by the animation of the non-living. The routinization of work makes mechanization possible, and subsequently is further imposed through mechanization. The sophistication of the capabilities of computers and automatic machinery develops in tandem

with the abstraction and simplification of ever-broader swathes of human activity. The standardization, fragmentation, and control of living organisms are achieved by the granting of increasingly lifelike qualities and capacities to the non-living. So we have technologized life and lifelike or “living” technology.

Drexler’s designation of this living technology as “self-replicating capital” and “productive capital” is an analytical insight, the critical implications of which he himself cannot develop. The infusion of capital with life is accompanied by salvationist rhetoric in techno-futurist thinkers like Drexler, Moravec, and Kurzweil and is fundamental to their images of endless expansion and technological progress. As Cooper has argued, the technologization of life through biotechnology has been crucial as a way of maintaining the idea of the progressiveness of capitalism, against the challenge posed both by the threat of economic stagnation and by environmental consciousness of “limits to growth.” Although seemingly far-fetched, the technological salvationism of thinkers like Drexler, Kurzweil, and Moravec expresses assumptions that are in fact pervasive in the ideology of modern technoscience. Today, as political or regulatory solutions to climate change are stymied by entrenched capitalist interests and by the anarchic international system of nation-state competition, hopes for a solution are increasingly vested in a technological fix, through geoengineering, however fantastical such technological solutions appear (York, Clark, & Foster, 2009, esp. pp. 14–15). What geoengineering augurs is potentially the radical technologization of the planet’s geophysical processes (solar reflectors in space, etc.). This would mean that the Earth itself becomes a capital-intensive system, requiring huge investments of capital to maintain its life-supporting systems. The common milieu of life, making possible all production and reproduction, is thus potentially transformed into an artificial milieu, dependent on and intertwined with capital. At the macro-scale of the Earth system, as well as the micro-scale of the genetic code, the reproduction of life is appropriated by, and subordinated to, the reproduction of capital.

The reification of the living and the animation of the non-living tend toward the environmental degradation of Earth so that life is no longer self-sustaining. For equilibrium, sustenance, and the promise of a future, the technovisionaries encourage us to look instead to the powers of capital, expressed in technological miracles of geoengineering, life in outer space, or uploadable intelligence. The renewal of capital as self-replicating, productive, self-valorizing value takes over from the renewal of life. Or, rather, the renewal of capital becomes the precondition for the renewal of life. Marx wrote in Volume 3 of *Capital*:

With the development of relative surplus-value in the actual specifically capitalist mode of production, whereby the productive powers of social labour are developed, these productive powers and the social interrelations of labour in the direct labour-process seem transferred from labour to capital. Capital thus becomes a very mystic being since all of labour’s social productive forces appear to be due to capital, rather than labour as such, and seem to issue from the womb of capital itself. (Marx, 1967, p. 827)

As the powers of the living are annexed to technology, an asymmetric symbiosis with capital is increasingly imposed on the living world. Capital becomes the artificial womb for life. The condition of “living dead species” abstracted from their living milieu, surviving in an artificially preserved commodified form, comes to characterize life in general. Marx described capitalism as an inversion through which living labor is appropriated for the augmentation of dead labor, and dead labor rules over the living. The capitalist “vampire” sucks the living activity of the worker (and, we should add, of the broader natural world), and from this it appropriates and takes on the characteristics of life. Living death describes the character of capital itself as self-valorizing value. As labor and life are subsumed by capital, this condition of living death is also generalized. This is the meaning of artificial life on a dead planet.

NOTES

- 1 Obviously, techno-enthusiasm has characterized much of the science fiction genre (e.g., Isaac Asimov and Arthur C. Clarke), and the techno-futurist discourse of robotics and nanotechnology enthusiasts often references or overlaps with such techno-optimist science fiction (Milburn, 1958, esp. pp. 39–58).
- 2 The concept of abstract life is implied also by Melinda Cooper’s discussion of organ transplantation as an abstraction of the “livable time of the organ” from the body (Cooper, 2008, p. 126). The idea that abstract life is closely related to abstract labor is also, I think, implied by Eugene Thacker’s analysis of “biomaterial labor” and of biotechnology’s “economic uses of ‘life itself’” (Thacker, 2005, p. 202).
- 3 See Boston Dynamics, <http://www.bostondynamics.com/> and the RiSE Project, <http://kodlab.seas.upenn.edu/~rise/newsite/index.php?leaf=1>
- 4 Drexler is also an enthusiast for cryogenic freezing as “insurance” against loss of species (Drexler, 1986, p. 123).

The Dead-End of Consumerism

The Role of the Media and Cultural Industries

Justin Lewis

ABSTRACT

In this chapter, Justin Lewis argues that twenty-first-century consumer capitalism is no longer an effective model for human progress. In developed countries, consumer capitalism can no longer deliver improvements in quality of life, is fraught with economic contradictions, and will make the planet considerably less habitable. How might we begin to address these issues and imagine a better world? Lewis focuses on three ways in which the contemporary cultural industries keep us conceptually bound to a consumerist credo. First, the media and communications industries have come to epitomize the notion of built-in obsolescence based on a perpetual consumerism. Second, our most dominant cultural industry, advertising, provides a cultural environment that makes it hard to imagine a way of being outside consumerism. Third, the capacity of journalism to question current orthodoxy is constrained by a focus on “disposable news,” displacing the more democratic function of journalism.

We are, in a sense, living in the future. Not our future, but at the beginning of a century that has been imagined and reimagined countless times over the last hundred years. Our predecessors would have been enthralled by possibilities we now take for granted: the revolution in information, communication, and cultural technologies has made what once seemed magical part of everyday life.

And yet the technology and consumer products that were supposed to free us from drudgery, ignorance, and toil have also created a new set of burdens. The demand for gadgetry and goods has become relentless, and the gradual decrease of hours in the working week that defined much of the twentieth century has come to a shuddering halt (Schor, 1991). The model of perpetual growth that created this largesse requires endless effort to keep pace with it. But there is also an understanding that the way we live now is, for all its abundance, full of empty promises (James, 2007).

This chapter begins by exploring why consumer capitalism, as a model for human progress, has become dysfunctional. For Marx (1976), the contradictions of capitalism lay in the drift toward monopoly and the prospect that the in-built division between owners and workers would foment popular discontent. The survival of consumer capitalism into the twenty-first century suggests Marx underestimated capitalism's adaptability – in negotiation with the state and a growing public sector – but it has created a new set of contradictions. These are more than mere quirks: they represent profound problems across a number of environmental, economic, and cultural fronts. While these may not bring about its downfall – capitalism, aided by government, has shown a capacity to endure contradiction – they oblige us to ask whether there might be a less acquisitive and more fulfilling model of human society.

The chapter then considers why the mainstream public sphere finds it so difficult to acknowledge these contradictions, let alone address them, focusing on three ways in which the contemporary cultural industries keep us conceptually bound to a consumerist credo. First, the media and communications industries have come to epitomize the notion of built-in obsolescence based on a perpetual consumerism. Second, our most dominant cultural industry, advertising, provides a cultural environment that makes it hard to imagine a way of being outside consumerism. Third, the capacity of news journalism to question current orthodoxy is constrained by a focus on “disposable news,” displacing the more democratic function of journalism.

Environmental Contradictions

After centuries of growth, humankind now consumes resources at a rate that matches the scale of the Earth. Natural resources dwindle as demands made upon them increase (McKibben, 2006). Although science has become increasingly adept at anticipating these ecological pressure points (witness, for example, the rise of climate science), our society is inept at addressing the contradiction between an economic model based on infinite expansion and a finite Earth.

The list of environmental problems created by this clash is daunting. We produce waste at an unprecedented rate, contaminating the soil, the air, and the sea. We wipe out ecosystems and species to make space for greater productivity. But most daunting of all is the realization that one of the key byproducts of our enormously productive economy is a series of gases that threaten to alter life on Earth.

For over two decades, the Intergovernmental Panel on Climate Change (IPCC) has published and evaluated an increasing body of evidence that has made the case for anthropogenic global warming irrefutable. Meanwhile, in a collective act of brinkmanship – as if to test the theory to breaking point – we have continued to pump an ever-increasing volume of greenhouse gases into the air (Lewis & Boyce, 2009).

By the time the IPCC issued its fourth assessment in 2007, the question was no longer one of preventing climate change but of ameliorating its worst effects. In practical terms this means keeping the likely death toll – from disease, famine, drought, and the increased likelihood of extreme weather events – to millions rather than billions. Seventeen years after its first report, the IPCC documented not only that the various efforts around the world to tackle climate change have failed to stabilize our greenhouse gas production, but that current mitigation policies will allow that production to increase to unprecedented levels (IPCC, 2007, p. 44). Although the IPCC continues to stress that “many impacts can be avoided, reduced or delayed by mitigation” (p. 69), it is clear that we are running out of time.

The stakes could scarcely be higher. So why is it that, in the face of one of the greatest challenges to humankind, our political leaders seem content with a series of half-measures? The collapse of global climate change talks in Copenhagen at the end of 2009, for example, was greeted with little sense of alarm. A few months later, a BBC survey in February 2010 found that only 26% of British people agreed with a statement that reflected the scientific consensus: “climate change is happening and is now established as largely man-made” (roughly the same proportion who believed that “climate change is not happening” at all).¹ This was actually a drop from the previous year’s figure. The Pew Research Center for the People and the Press in January 2010 found that dealing with climate change was bottom of a list of 21 priorities for government, with only 28% judging it to be a priority (a fall from 38% in 2007).²

At the heart of this inertia is a paradox: our apparent acceptance of the threat posed by climate change is occurring at a time when we have become increasingly risk averse. The influential sociologist Ulrich Beck has famously described countries in the developed world as “risk societies” (Beck, 1995, 1999), where fears of everything from terrorism to pedophilia tend to be amplified into a clamor of overreaction (Lewis, 2006). We live in a time, he suggests, when concerns about health and safety involve systematic attempts to reduce risks to a minimum, and where exaggerated fears of minimal risks – sometimes based on the feeblest of evidence – can induce panic, with very real consequences (see Boyce, 2007, on the MMR vaccine scare in the United Kingdom, where media scare stories significantly reduced the takeup of the vaccine and reduced immunity levels).

As climate science has become ever more certain, our muted reaction to it remains a vexed question (McGaurr & Lester, 2009). There are a number of explanations: the difficulty of appreciating a problem on a global scale, the time lag between cause and effect, and political systems where governments have little incentive to address

issues whose manifestations will not be their problem, given the time span of elections.

But perhaps the most fundamental reason for our failure to come to terms with climate change is the credo expressed so vividly by marketing consultant Victor Liebow in the 1940s. Consumer capitalism, he suggested, requires things to be “consumed, burned up, worn out, replaced, and discarded at an ever increasing rate” (in Packard, 1960, p. 33). It pushes us toward individual acts of consumption rather than collective problem solving.

It would be unfair, perhaps, to blame consumer capitalism for getting us to this point: we can have economic growth and environmental degradation without consumer capitalism, and there is no doubt that the prosperity it has helped create has brought many advantages. But it would be naïve to suppose that the “invisible hand” is capable of the kind of altruistic planning necessary to avert catastrophic climate change. As it now stands, consumer capitalism seems more likely to push us past the “tipping point.”

Economic Contradictions: The Diminishing Returns of Consumer Capitalism

Economic historian Avner Offer (2006) suggests that this superabundance, far from easing our lives, *creates* a series of problems. The more choices we are asked to make, the less time or resources we have to make them. In the land of plenty, the “rational consumer” – that beloved creature of classical economics – may conclude that the time and effort involved in finding the best product at the best price exceed the rewards of making the right purchase. In short, rational consumers will make rational decisions to give up being rational, opting, instead, for an easy life and resigning themselves to making hurried purchasing decisions. This is consumer capitalism’s catch-22.

The proliferation of commodities, Offer suggests, is as much a source of stress as a pleasure, pushing people toward overconsumption (which is the easiest response to an abundance of goods) and thereby diminishing quality of life. This submission to a series of decisions without deliberation involves a loss of self-control, thereby limiting our ability to act independently. In an era of superabundance, the ratio between choice and time stretches to alter the mechanisms of consumer capitalism, to a point where increasing choice becomes dysfunctional.

In a similar vein, the law of diminishing returns – which tends to be applied to systems of production – can equally be used to describe the logic of consumption. Consumer capitalism is predicated on the simple idea that our lives improve in proportion to the accumulation of consumer goods. But its ability to deliver on this promise is unsustainable. As our level of security, comfort, and amusement

increases, we experience what economists refer to as the diminishing marginal utility of goods and services: the pleasures of accumulation, in other words, *decrease* with every purchase. The more we have, the less value each new possession will have.

So, for example, someone with only two pieces of furniture will attach significant value to acquiring a third: partly because it will fulfill a need, but also because it represents a substantial increase in her ability to furnish her home. To someone with 102 pieces of furniture, a new acquisition is of less value – both because the need for it is less pressing and because it represents only a tiny increase in her stock of furniture. As Colin Campbell (1989) has argued, classical economics struggles with this idea, since it cannot “account for the nature or origins of wants and tastes, and offers only the most attenuated suggestion concerning why people buy goods” (p. 40).

This is not to deny the pleasure that new things can bring, simply to understand that the pleasures of consumerism are neither pre-given nor infinite. In the twenty-first century, most people in the developed world have reached the point where the constant accumulation of consumer goods has become a diverting (sometimes pleasant, sometime not) but unnecessary habit. Economists (notably J. K. Galbraith, 1958), philosophers (such as Herbert Marcuse, 1964), and journalists (most famously, Vance Packard, 1960) questioned the nature of need in a consumerist society half a century ago. We do not have to accept Marcuse’s rather austere distinction between “true” and “false” needs to appreciate that advanced consumerism is a system in denial of one of the simplest economic (and emotional) probabilities of the human condition: the more we have, the less we need. Just as the cost of goods decreases with volume, so does their value.

But the diminishing returns of consumer choice are deeply repressed. Our current model of consumerism is obliged to cling resolutely to the same promise with every purchase. The idea that each new object we acquire is, by definition, *less* valuable than the last is not just a lousy sales pitch, it begins to undermine the whole consumerist enterprise. For the system to survive, we must imagine that the pleasures of accumulation are endless. It is an expensive pretense.

Can consumer capitalism survive without endless growth? The easy answer to this is no, although this may be because the possibility is rarely explored. Nonetheless, an increasing number of economists, such as those at the New Economics Foundation, are challenging the principle of economic growth in wealthy countries. They see the current model of economic growth – measured in terms of gross domestic product (GDP) – as both crude and amoral: a place where war (which creates demands for weaponry as well as the need to rebuild what is destroyed) is better than peace (which creates no demand) and where waste is a virtue.

Because of such glaring absurdities, the New Economics Foundation proposes that we abandon GDP as a measure of social progress, replacing it with a series of indicators that better describe human fulfillment and quality of life. This, in turn, raises the third problem with consumer capitalism: despite the promises of plenty, it no longer has the capacity to deliver the things that we most value.

Cultural Contradictions: Consumer Capitalism vs. the Quality of Life

As critics of consumerism point out (see, e.g., Jhally, 1990, 1998), there is a contradiction between our desires, which tend to be social rather than material, and consumer capitalism's provision, which is simply material. Or to put it another way, we have trashed the planet and mortgaged our futures on the hope of infinite growth, yet all we have to show for it is a mountain of consumer goods. People may have had fun using them, they may even have had fun buying them, but they remain unfulfilled by the pleasures of accumulation.

Things are *supposed* to keep getting better – this is, after all, the promise of a consumer society. But there is an increasing body of evidence from across the social sciences that suggests that the link between quality of life and our ability to consume is fictitious. Richard Layard (2003), summing up the research on quality of life, puts it bluntly: “People in the West have got no happier in the last 50 years. They have become much richer [. . .] But they are no happier. This shocking fact should be the starting point for much of our social science” (p. 14).³

Layard's assertion, for all its boldness, is too modest. The revelation that quality of life has little to do with our access to consumer goods runs so counter to contemporary conventional wisdom that it should be the starting point for our culture, our economics, and our politics.

And yet the idea that human progress is directly proportional to our ability to buy remains deeply rooted in our politics and our popular culture. Every government, regardless of political hue, is committed to economic growth on the assumption that all else – happiness, security, and human progress – flows from it. The idea that we might begin to think more directly about providing the conditions for happiness, fulfillment, and security, and that we might think more deeply about what human progress actually means, seems almost a distraction. In essence we are all bound to a system that treats us like spoilt children who just want more stuff and better stuff. And, like spoilt children, we are no happier for it.

Tim Kasser's (2002) review of the literature on the psychology of materialism suggests that far from providing happiness or fulfillment, materialist values are associated with a *drop* in quality of life. Similarly, Juliet Schor's study of children and consumerism suggests that “less involvement in consumer culture leads to healthier kids and more involvement leads kids' psychological well-being to deteriorate” (Schor, 2004, p. 167). Her research suggests that immersion in consumer culture is the key explanatory factor associated with various forms of unhappiness in childhood.

The paradox, for some social scientists, is that *within* a society income is related to quality of life (Oswald, 2003). But this is easily explained: briefly, in a society that links income with status, people like to feel they are doing well rather than doing

badly (Layard, 2003). In other words, those on higher incomes are happier than those on lower incomes because of the respect and satisfaction that accrue from their relative position, *not* because they have more stuff.

Wilkinson and Pickett (2009) have taken this idea one step further. They provide striking evidence of the problems caused by creating wealth without equality. Their extensive review of the literature shows a relationship between distribution of income and resources and quality of life. The greater the level of inequality in a society, the greater the level of discontent. So, for example, countries like the United Kingdom and the United States, where the gaps between rich and poor are fairly high, measure poorly on the indices of quality of life when compared to the more egalitarian Scandinavian countries.

It is hard to overstate the significance of the quality of life research. The whole premise of consumer capitalism is based on the notion that the accumulation of objects improves the quality of our lives. And yet when this idea is put to the test, it is found wanting. This would matter little if we set no store by it, but consumer capitalism is one of the organizing principles of twenty-first-century society. It absorbs our time, our energy, and our political imagination.

Living the Contradictions: Media, Culture, and Consumer Capitalism

So why do we remain so deeply committed to a system whose benefits are increasingly limited, whose promises are exhausted, and whose environmental consequences look increasingly dire? Why do we embrace a way of life that makes us no happier or fulfilled, is fraught with contradictions, and will make the planet considerably less habitable? And how might we begin to address these issues and imagine a better world?

Our failure to change course is rooted in a set of cultural practices, all of which push, nudge, and cajole us down a consumerist *cul-de-sac*. These practices are so much a part of everyday life that they get in the way of a more deeply felt, sophisticated appreciation of just what it is that constitutes human progress and makes life worth living. Central to these practices, I suggest, are the commercial giants of media and telecommunications. For all their moments of brilliance and profundity – and, whatever the Jeremiahs may say, there are plenty of them⁴ – our information and entertainment media have become increasingly suffused with ideas that sustain consumerism and sideline alternatives. None of these practices is inevitable or irreplaceable, but unless we rethink them it will be difficult for us to imagine any other form of society. I shall focus, here, on three ways in which a largely commercial media and telecommunications sector limits our cultural environment.

Obsessed with Obsolescence

The aviation industry has received plenty of flak for its production of greenhouse gases. Environmental groups like Plane Stupid in the United Kingdom protest against airport expansion (Doyle, 2009) while the concept of “air miles” has become part of the environmentally aware lingua franca. Many of those who have calculated their “carbon footprint” will be aware that the most palpable way to reduce their emissions is to fly less. And yet, with far less fuss or scrutiny, the media and communications industries spew out the same level of carbon emissions as aviation (Gartner, 2007). This may seem counterintuitive, since the aviation industry’s core business involves burning large quantities of fossil fuel, while sounds and images are more ephemeral. Without a major technological shift, the growth of aviation was always going to be environmentally damaging. The growth of media and telecommunications, on the other hand, might have used sophisticated postindustrial technology in very different ways.

Instead, the media information industries have achieved a level of built-in obsolescence that is the apotheosis of consumerism at its most profligate. As Jonathan Sterne (2007) points out, this is a sector where “obsolescence is not only planned but also forced and engineered” (p. 7). With every passing decade, the various bits of hardware that bring us information and entertainment have a shorter shelf-life. Computers, mobile phones, and electronic entertainment devices are designed to become antiquated with a speed we would not tolerate with other household appliances (Maxwell & Miller, 2009), while technologies for relatively simple pleasures, like playing music or making a phone call, now occupy the same kind of temporality as fashion accessories. While traditional telephones have become emblematic of particular decades of design, US consumers now replace their cell phones once every 12 months (Crosby, 2007) – a level of built-in obsolescence that once would have been unthinkable.

This is hyperconsumerism – a system that tells us not only that we need to surround ourselves with new things, but also that we need to constantly replace what we already have. In the space of 10 years, televisions switched from analog to digital, changed shape to a wider screen, changed shape again to a flat screen, only to be reconfigured once more to various higher definitions of image (which, in turn, require a larger screen to be appreciated). The most recent incarnation – 3D TV – arrives on the scene as the latest installment on this breathless path of constant reinvention.

In the United States, the Consumer Electronics Association calculated that the average US household in 2008 spent over \$1,400 per year on a total of half a billion consumer electronic devices (Brugge, 2008). With almost every stage these devices have tended to become *less* energy efficient, each new gadget or appliance eating up more power than the thing it replaced. In the United Kingdom, sales of flat-screen TVs have been estimated to increase the carbon emissions involved in watching TV by 70% between 2006 and 2010 (Maxwell & Miller, 2009).

The most conspicuous outcome of this hyperconsumption – the vast accumulation of e-waste – is hidden from the view of most Western consumers (Hawkins, 2003). The United States alone dumps 300 to 400 million electronic items per year, and less than 20% of that e-waste is recycled (only 2% of PCs are fixed, upgraded, or passed on to a second user). By 2005, for every new computer manufactured in the United States, one became obsolete (Sterne, 2007, p. 10), while the United Kingdom dumps 1.5 million PCs in landfills every year (Maxwell & Miller, 2009).

The waste from televisions, monitors, laptops, portable DVD players with LCD screens – and many other playthings of the information age – is highly toxic, making disposal or reuse of the more valuable minerals a hazardous business. To cut costs, e-waste is often exported to countries with cheap labor and lax environmental laws, with dismal consequences for the health of those involved (Gabrys, 2007; Maxwell & Miller, 2009). At the beginning of the twenty-first century the electronics industry was, according to the Basel Action Network (BAN, 2002), “the world’s largest and fastest growing manufacturing industry, and as a consequence of this growth, combined with rapid product obsolescence, discarded electronics or e-waste is now the fastest growing waste stream in the industrialized world.”

Despite the sleek designs of many telecommunications devices, they are resource intensive to produce. Unlike many home appliances, four times as much energy is spent on making devices like computers or flat-screen TVs than on using them (Williams, 2004). So, for example, the manufacture of a desktop computer and monitor requires 530 pounds of fossil fuels, 50 pounds of chemicals, and 3,300 pounds of water – roughly the same use of resources used in the manufacture of a large automobile (Kuehr & Williams, 2003). The manufacture of computers and mobile devices, digital cameras, and other devices is a dirty business: “If you dig down beneath the thin surface crust of Silicon Valley,” writes Jennifer Gabrys,

you will find there are deep strata of earth and water percolating with errant chemicals. Xylene, trichloroethylene, Freon 113, and sulphuric acid saturate these subterranean landscapes undergirding Silicon Valley. Since the 1980s, 29 of these sites have registered sufficient levels of contamination to be marked by the United States Environmental Protection Agency as Superfund priority locations, placing them amongst the worst hazardous waste sites in the country. [. . .] Of the 29 Superfund sites, 20 are related to the microchip industry. (2007, p. 1)

In short, the information age is built on submerged mountains of toxic waste, an unsustainable use of resources, and dependence on fossil fuels. While some might see this environmental impact as the inevitable cost of progress, this is not a sufficient rationale. The breakthroughs in information and entertainment technology *might* have created a cleaner, smarter, more democratic world. Instead, the industries that have profited from these technologies have contrived a level of built-in obsolescence few other industries can match. Media and telecommunications are thus in the vanguard of a consumerist ecology. They have succeeded in making the idea that

things should be “consumed, burned up, worn out, replaced, and discarded at an ever increasing rate” (Liebow, in Packard, 1960, p. 33) seem a natural part of modern life.

There is no doubt that, in the last two decades, there have been rapid leaps forward in digital communication. But to what end? The genius of modern communications has, all too often, been tied to the banality of a cost-effective culture. Despite the constant reinvention of our TV screens, it would be hard to argue that the quality of the programs we watch has improved a great deal over the last decade, if at all. Indeed, the proliferation of television channels is sustained by a commercial model that depends upon the large-scale recycling of old programs – not a bad thing, in itself, but hardly in keeping with the relentless updating of television gadgetry.

Many of the new technologies are sold to us on the basis of a better quality of sound and image. But the permanent revolution in electronic information and entertainment has as much to do with product proliferation and convenience as with technological progress. So, for example, the poor-quality speakers on most components – from digital radios and TVs to DVD players and iPods – produce sounds that are demonstrably cruder than an above-average stereo system manufactured 30 years ago. There is a *kind* of progress here, but it is often narrowly defined around the aesthetics of the consumer object, without any sense of television’s greater social, democratic, or cultural potential.

So, for example, the enthusiasm for digital television often highlighted its potential for interactivity: television would no longer be a top-down technology, proclaimed enthusiasts, but one where interactivity would lessen the gap between producers and audiences. Here was technology bringing power to the people at the press of a red button. And yet the democratic potential of interactive digital television remains largely ignored, especially by commercial media, which quickly discovered that, beyond charging people for votes in reality television shows, there was no money in it (Curran, 2010).

What is remarkable, in many ways, is the ease with which we have accepted – even embraced – this level of built-in obsolescence, while being fairly oblivious of its environmental consequences. Take, for example, the move toward digitization in radio and television. Governments have promoted such a move, and while the benefits of digitization are repeatedly lauded, the environmental costs of switching to a digitized system are routinely ignored. The UK government is anxious to *force* a switch from analog to digital radio, despite the fact that consumer demand for a new system of reception remains lukewarm. Millions of appliances will become obsolete at the flick of a switch, while simultaneously *increasing* the energy required to power a radio set (thereby decreasing their portability, and ending the recent development of wind-up/solar-powered radios).

From consumer capitalism’s point of view, the beauty of the current model is to create a public so accustomed to the constant production, reproduction, and renewal of media technologies that we see this, *in itself*, as a mark of progress. This is not to say that the industry’s innovations have been pointless – there are plenty of jewels amidst the junk – simply that the imperatives of consumer capitalism have pushed

us *away* from exploring (and developing) the social value of these technologies and *toward* the accumulation, and replacement, of objects. The communication and entertainment businesses are, in this sense, at the cutting edge of consumerism. Their role is, in this context, both material and ideological.

The relationship of media and communications to consumer culture is bolstered by the way we have allowed the content of media to be increasingly dominated by advertising. Most of our information and entertainment media – newspapers, magazines, radio, and television – are not simply funded by advertising; commercials *dominate* their output. On television, the proliferation of channels has been driven largely by commerce, so that the proportion of publicly funded spaces has shrunk with alarming speed (Pauwels, 1999; Rowland & Tracey, 1990; Tracey, 1998). The United Kingdom, for example, has moved from a carefully constructed ecology based on public service – with a small number of well-funded channels producing a wide range of high-quality programming – to a commercial system with a politically fragile public service component (the BBC and a small and increasingly reluctant group of commercial networks) and a plethora of commercial channels all chasing a limited revenue stream. This combines with a lax regulatory environment, so that advertising now takes up a higher proportion of UK television programming than at any time in its history.

Genres, like film, that were traditionally advertising-free spaces are now funded by product placement deals and commercial tie-ins. Advertisements wallpaper our public spaces – on billboards, buses, and buildings – and brand the clothes we wear. All our communications media – the mail, the Internet, social networking sites, even phones – are increasingly channels for pitching products. As each medium becomes saturated, advertisers look to invade new spaces with a voracious energy that threatens to colonize the entire cultural landscape.

Advertising has thereby become our most dominant cultural discourse, permeating almost every medium, every cultural space. Despite its manifest dominance, contemporary media, communication, and cultural studies has devoted remarkably little time to the role of advertising in sustaining consumer culture, and it is to this issue that I now turn.

Selling Consumerism

Around the middle of the twentieth century, it became increasingly clear that the main problem facing consumer capitalism was not one of production but of consumption (Jhally, 1998). The abundance of goods, it appeared, may have satiated demand (Packard, 1960): the economist J. K. Galbraith, writing in 1958, marked this period as a time when “the urgency of the wants can no longer be used to defend the urgency of the production” (Galbraith, 1958, p. 127).

There are, after all, other pleasures that come with affluence – notably the freedom and opportunity of more leisure time. Once they were free from want, many people sought to loosen the confines of long working hours. At this point, had we decided to spend our money on buying (free) time rather than more consumer goods, consumer capitalism might have been obliged to turn its attention to producing goods for those in greater need. But the machinery of consumer capitalism is not built for altruistic purposes. In practical terms, there is more to be made in selling superfluity to the rich than necessities to the poor. This meant pouring resources into an industry whose sole purpose was to produce what the system craved – an inexhaustible demand for consumer goods. The advertising industry was thus charged not simply with selling goods, but with selling consumerism. Or, as retail analyst Victor Liebow put it in the late 1940s, making consumption “our way of life,” converting “the buying and the selling of goods into rituals, [so] that we seek our spiritual satisfaction, our ego satisfaction in commodities” (in Packard, 1960, p. 33).

The advertising industry had, for some time, celebrated the inequity that those in greatest need of its services were those with the greatest resources. It now found itself as the propaganda wing of an economic system – perversely, an industry whose importance grew as people’s need for consumer goods diminished. Indeed, the success of advertising in promoting consumer goods created a cycle of dependency. As the volume and range of products proliferated, consumers became increasingly dependent upon advertising to differentiate one product from another.

Advertising, in this sense, is not just another cultural industry. While scholars like Neil Postman (1985) have tried to advance Marshall McLuhan’s famous theory that “the medium is the message,” most forms of communication are ideologically ambiguous. Television, for example, may have certain characteristics and properties (Ellis, 1992), but as a technology it is comparatively value-free. It can be consumerist or environmentalist, capitalist or socialist, feminist or patriarchal. Advertising can also entertain forms of ambiguity – the feminist critique of advertising (Wolff, 1991; see also Kilbourne’s canonical critique in Jhally, 2000), for example, allows us to plausibly imagine an advertising industry that does not depend on gender stereotypes. But there is no escaping the place where form and content collide – advertising is closely bound to the ideology of consumerism.

Yet advertising is generally regarded – certainly by governments and regulatory bodies – as entirely apolitical. So much so that, in certain contexts, advertisements *with* an overt political message are seen as problematic (and, in countries like the United Kingdom, in breach of broadcasting codes on impartiality). This is, in part, because we are used to locating meaning – whether it is a TV commercial or a TV program – in individual texts. But the ideological thrust of advertising is precisely in its collectivity. As individual stories they have a certain innocence. Their systemic meaning, on the other hand, is at the heart of a consumerist ideology (Mander, 1977). The moral of the thousands of different stories they tell is always the same: regardless of how much we already have, the only way to pleasure, popularity, security, happiness, or fulfillment is through consumption.

Television or radio programs may vary, but commercials themselves are, for all their symbolic excess, remorselessly repetitive. This is not a new observation, and yet the *systemic* meaning of advertising is often glossed over or ignored in media and communication studies. Despite the industry's extraordinary growth and ubiquity, we see few attempts to come to terms with the magnitude of advertising as a cultural system.

The failure to interrogate the political significance of advertising and its role in consumer culture is rooted in a rejection of early Marxist approaches to contemporary culture. Any systemic critique is often reduced to a set of Marxist origins, whereby advertising is seen as linked to a set of economic imperatives in which the realities of the conditions of production are suppressed. Such a critique is often dismissed as reductive at a time when Marxist approaches have become deeply unfashionable. There are three problems with this dismissal.

First, although many Marxist analyses of culture may be too crude to appreciate what cultural studies scholars used to call the "relative autonomy" of cultural forms, this was partly because production practices – in, say, the television or film industries – were often only loosely tied to economic imperatives. So, for example, commercial films needed to make money, but this did not mean they had to promote the economic system that produced them. In countries with a strong tradition of public service broadcasting, the relations between culture and economy were more complex still.

The advertising industry, however, is decidedly *less* complex. For all their occasional wit and panache, advertisements are profoundly functional – unlike most cultural forms where the relationship between content and consumption is less direct, they exist to promote consumption. What was compelling about the critiques of a Marxist approach to culture was the rejection of a totalizing theory that ignored the specificities of cultural production. But ironically, this rejection has its own reductive quality, whereby *any* attempts to connect economy and culture are rejected. This denial of the connections between economy and culture has led to a failure to appreciate those instances where such a relationship is pivotal, especially in advertising.

Second, this rejection spawned a media and cultural studies that focused on ambiguity and complexity. Advertisements are often rich with meaning: they can be seen as playthings in a semiotic democracy that cannot be reduced to a simple economic function, and where meaning is never guaranteed. And, as many critics of advertising point out, there is no doubt that advertisements do far more than communicate messages about consumption (Williamson, 1995). However, such an appreciation does *not* mean that advertising's consumerist logic is somehow irrelevant, that other meanings are created while the promotion of consumption is ignored.

All too often, the idea that advertising plays a role in promoting consumerism is parodied as a reductive "hypodermic needle" theory of media influence, whereby witless, passive citizens are commanded to go forth and accumulate. But the dismissal that follows this parody is far too easy. The discourse of advertising can be powerful without being totalizing, unambiguous, or passively received. Indeed, to suggest that

such a ubiquitous industry devoted to extolling consumption has played no part in the development of consumer culture is frankly perverse. Even Michael Schudson, regarded by critics like Stuart Ewen as an apologist for the industry, suggests that the advertising industry “may shape our sense of values” (Schudson, 1986; Ewen, 2001).

Third, the observation that advertising portrays a world in which the production and distribution of commodities are either romanticized or (more routinely) ignored may have its origins in a Marxist analysis of the relations of production. But it has long since surpassed these origins, encompassing many other critiques – Naomi Klein’s *No Logo* (1999) and the Fair Trade movement being the best known – which address gender inequalities in production, child labor, the inequities of globalization (where production shifts to where labor is cheapest), the environmental costs of production and distribution, and the growing problems of post-consumption (the disposal of our toxic array of consumer goods).

Again, what is common to most advertising is that it bypasses inequities of global production and the environmental consequences of production, distribution, and disposal, to stress the moment of consumption with remorseless repetition. In this sense, advertising is on one side of a wide-ranging and very contemporary political argument with feminists, labor activists, environmentalists, and the anti-globalization movement. While at times this opposition is overt – the case of “greenwashing” campaigns, for example – advertising’s significance is less a matter of persuasion than its ability to keep changing the subject, to return our focus toward the pleasures associated with what Sut Jhally (1998) calls “the dead world of things.”

Because we have allowed advertising to become our most dominant form of cultural expression, it crowds our imaginations and makes it difficult to contemplate a society that is *not* based on consumerism. If, as Tim Edwards suggests, “consumerism as an ethos and a practice is expanding in importance at a near exponential rate to incorporate everything from health and insurance to education and recreation” (Edwards, 2000), it is entirely in keeping with advertising’s voluminous colonization of the communication, information, and entertainment industries. This could, of course, be coincidental rather than causal – causality is, after all, much easier to quibble with than to establish (Lewis, 2008) – but it stretches credulity to suggest that such a ubiquitous cultural discourse has little ideological impact.

Above all, the growth of advertising – the knotweed of contemporary culture – is not innocent or apolitical. Its presence pushes us further down the dead-end of consumer capitalism and offers no way out. As Richard Layard (2003) suggests, legislation *banning* advertising is a far more sensible policy for increasing quality of life than extending consumer choice. Such a policy is, of course, politically implausible (and probably undesirable), but we do need to consider the positive social outcomes of living in a world less dominated by the discourse of advertising. This involves radically rethinking of current approaches to funding the creative industries, which push us toward increasing rather than decreasing the cultural space occupied by advertising.

Disposable News and Democracy: Rethinking the Way We Report the World

In theory, the news is a place where the shortcomings of consumer capitalism – its failure to deliver an improved quality of life, its environmental consequences, and consumerism’s diminishing returns – might be highlighted and debated. And yet a tired orthodoxy prevails. Despite the growing number of critiques of a crude model of economic growth (measured in GDP), the news media’s economic framework is as robust as it ever was, solidified by the growing genre of business reporting.

There are, of course, negative consequences if the wealthier people of the world spend less money. But this is because we have designed an economic system that depends upon debt-led consumerism, where production is tied less to human need than to the demands of a consumer economy. For example, developing nations are encouraged to export commodities rather than become self-sufficient, tying them to the vicissitudes of global capitalism. A drop in global demand is bad for these economies because they have been encouraged (by institutions like the International Monetary Fund and the World Bank) to serve global consumers rather than local interests.

But the environmental, economic, and cultural critiques of consumer capitalism are becoming too persuasive and too powerful to be dismissed. As a consequence, it is no longer possible to assert the idea that “growth is good” as a simple objective truth. Any virtue attributed to growth depends on how it is measured, managed, or achieved. It follows that some forms of economic growth may *not* be good, while many of the conditions for positive human progress lie elsewhere.

Many of these points are given an airing in news programs, but they are usually confined to the spaces reserved for quirky, counterintuitive ideas. Climate change, meanwhile, even when it is taken seriously, tends to be portrayed as a technological rather than a systemic problem. News coverage tends to focus on solutions that involve refitting the growth model with a series of techno-fixes rather than questioning the nature of the model itself (Lewis & Boyce, 2009). Less consumption – which is almost certainly a necessary part of any attempt to offset the worst effects of climate change – is uniformly presented as *bad* news, rudely interrupting the model of endless growth. The news media find it hard to countenance an alternative to an economic system of borrow-and-spend, or an environmental model of consume-and-trash.

Why is this? In its ideal form, news occupies a *space outside* consumerism, addressing us as citizens rather than as consumers. In so doing it fulfills a deeply egalitarian purpose, to inform people about the world and enable them to make considered democratic choices. Many critiques of the news media – from the Glasgow Media Group (see, e.g., Philo, 1995) to Herman and Chomsky’s propaganda model (1988) – use this ideal as their point of departure. This utopian model of journalism remains palpably intact, immediately understood by both journalists and critics.

The critical literature on news offers many explanations for journalism's failure to encapsulate Habermasian (1991) ideals of the public sphere – the dependence on elites, on well-worn frameworks, on public relations, and on business interests all compromise the news as a diverse, open, civic space. But part of the problem is also more fundamental: the style, content, and expectations of what defines “news” have been shaped by the needs of an emerging consumer culture.

Terhi Rantanen (2009) has written a compelling analysis of the way in which the news continually reinvents itself as “new.” We can use this framework to examine the purpose and utility of news as a public service and as a commodity form. The key term, in this analysis, is “disposable news,” a form of built-in obsolescence that serves a profit motive but impedes public understanding of the world – an idea that reaches its apotheosis in the repetitive rush of the 24-hour news cycle (Lewis, 2010).

At the same time, the history of journalism is inevitably intertwined with politics and, as Brian McNair suggests, with the rise of democracy (McNair, 2000). In early nineteenth-century Britain, the radical press was clearly an agent for democratic change and promoted the ideal of a universal franchise (Thompson, 1968), at a time when only a certain class of property-owning men could vote. For writers like Henry Hetherington, editor of the *Poor Man's Guardian*, news was, in part, about educating citizens and encouraging them to take history into their own hands.

James Curran and Jean Seaton (1997) and Kevin Williams (1998) argue that the decline of the British radical press was hastened by the government's adoption of a more liberal approach to news. Initial attempts to suppress the radical press were decidedly heavy-handed, with “taxes on knowledge” that effectively penalized all forms of popular journalism. The adoption of a more reformist, less punitive tax regime allowed the growth of commercial mass-circulation newspapers, requiring a level of capital investment and advertising support that favored more establishment forms of ownership. As a consequence, Curran and Seaton (1997) suggest, newspapers moved out of the hands of radical reformers and became big business, and thus “market forces succeeded where legal repression had failed in conscripting the press to the social order” (p. 9).

But it would be misleading to see the radical forerunners of mass-circulation news as high-minded purveyors of information about public affairs. As Stuart Allan (2000) and Jackie Harrison (2006) make clear, there was no golden age of reporting that was subsequently degraded by the grubby needs of commerce. The radical press may have championed democracy, but these newspapers were also bound by the need to make money and could muckrake with the best of them. Radical editor Henry Hetherington promised that one of his newspapers would deliver “Murders, Rapes, Suicides, Burnings, Maimings, Theatricals, Races, Pugilism and [. . .] every sort of devilment that will make it sell” (cited in Allan, 2000, p. 13).

Indeed, the democratic ideal of journalism, whereby news fulfills a deeply egalitarian purpose – informing people about the world and enabling them to make considered democratic choices – developed *alongside* the desire to titillate and

entertain. In the twentieth century, journalism in the United States, where governments have generally been deeply committed to keeping news in the hands of private enterprise, has also developed a strong *cultural* commitment to notions of fairness and objectivity.

Nonetheless, the growth of news as a business – its industrialization and absorption into capitalist production from the late nineteenth century onwards – created a distinct set of impulses. The style, content, and expectations of what we think of as “news” were quickly shaped by the needs of an emerging consumer culture. This meant a gradual shift away from news about public affairs toward crime, sport, and other “human interest” (Barnhurst & Nerone, 2001), but it also created a working definition of news based on the need to sell it as a *disposable commodity*. Once news became a manufactured product, its commercial success relied upon the creation of a transitory world where information can be quickly discarded and replaced, rather than a space designed to build common knowledge.

The history of journalism – like the history of media generally – is often understood as an inexorable process made possible by a series of demographic and technological developments. But if the growth of the daily newspaper was made possible by urbanization, the growth of transport networks, and efficient printing presses, its viability *depended on making news a constant celebration of the new*. As Terhi Rantanen (2009) points out, this is often more a matter of appearance than of substance. It became a necessary fabrication to be constantly up-to-date.

Journalism was thus partly defined, at a key stage in its development, by the notion of *built-in obsolescence*. The phrase “yesterday’s news” captures Victor Liebow’s consumerist credo perfectly. News loses its value not because it is no longer relevant or useful, but because it is past its sell-by date, quite literally. Its value, as a commodity, has less to do with its ability to inform than with its sense of immediacy. Indeed, we might say that consumer capitalism succeeded in making news the ultimate disposable item, one that needed replacing on a timescale even the fashion industry would regard as indecent haste.

Thus began a cultural economy based on the “thirst to be first” (Lewis & Cushion, 2009) – a point famously satirized by Evelyn Waugh’s *Scoop* in the 1930s. In this disposable world, newness is all. But in this context, what passes for new is rarely novel or original. The “shock of the new” in journalism is occasional rather than routine, and we are rarely offered ideas that change the way we view the world. News is new only in the banal, temporal sense that it is recent (and often not even then).

So while journalism retains a laudable sense of democratic purpose, it is constrained by its form: news became a commodity almost as soon as it was defined as news. Those in the newspaper business quickly understood that to become profitable, news has to become disposable. In essence, the more rapidly news could be made to appear out of date, the more regularly it could be sold. The newspaper thereby evolved into an object that represents a consumerist dream and an environmental nightmare – something that, *by definition*, needs replacing on a daily basis. The move to a 24-hour news culture has only sharpened the sense of news as a disposable commodity.

This political economy leaks into a philosophy. The idea that consumer goods should be built to last, rather than used up and replaced, has become almost passé, while we have contrived a world in which it is usually both cheaper and easier to replace something than to fix it. If journalism still has the capacity to go beyond this model, it is restrained by the degree to which it encapsulates it. Its currency is, in part, its currency. Journalism thus has a tendency to celebrate new *things* rather than new *ideas* (Lewis, 2010; Rantanen, 2009), a consumerist ideology that leads us back, inevitably, to a very limited, consumerist model of growth.

Indeed, the “growth is good” framework is so central to news storytelling about the economy that it pushes all conflicting concerns aside. Witness the way in which the problem of climate change was immediately sidelined during coverage of the recession from 2008 to the present. Part of the problem, of course, is that when economies are structured around a certain model of consumer capitalism, a recession will have negative consequences, notably for those who lose their jobs. But these problems are rarely balanced against the negative environmental (and human) consequences of growth, and there is almost no discussion of how rich countries might happily survive *without* economic growth.

The current crisis in journalism – prompted by the Internet, which has made it more difficult to sell news as a commodity – is both a threat and an opportunity. The danger is that news will become a cheap, mass-produced space designed to maximize market share, paid for solely by advertising revenue. In this scenario, the reputation of journalism will sink further in public esteem, and we can be sure that the contradictions of consumer capitalism will not be televised. But there is also a chance to refocus our attention on the democratic purpose of news, to recapture what elevates journalism as a profession and challenge a redundant system. Journalists themselves have a clear and vested interest in this, since the rise of “citizen journalists” and the mass production of news threaten their survival and the quality of their work.

Beyond Consumerism: Media Studies Reborn

The basis of my argument is that consumer capitalism has run its course: as a model for human progress it has become deeply dysfunctional. Unfortunately, any prospect that we might evolve to a more fulfilling, sustainable system is hampered by the way in which consumer capitalism has shaped the media and cultural industries. These industries both encapsulate and extol the wasteful and empty proliferation of commodities.

At the same time, they offer the potential to imagine a different model of human progress. A genre like news, for example, retains a commitment to criticism and debate in spite of its commercial genealogy. And while most cultural genres, from pop music to film, are now deeply tied to the selling of commodities, they remain

more open to the political imagination than the advertising that often funds or promotes them. If we are to progress, we might begin by rethinking the way we pay for and regulate our cultural environment. We have created sufficient wealth to do almost anything we want; we should stop and think about how best to use it. And to do that, we need a different set of stories.

Those of us in media, communication, and cultural studies are well placed to scope out these possibilities. This will, however, be neither easy nor straightforward. It means adopting a more critical attitude to production practices that create the beguiling array of media technologies we often use and whose potential we may find exhilarating. It means taking the ideological consequences of dominant media discourses like advertising seriously, rather than adopting the lazier course of critiquing any attempts to demonstrate the influence of our cultural industries (it is always easier to question power and influence than establish it) (Lewis, 2008). And it means embracing a form of journalism education that takes nothing for granted about the nature of news, while refusing to apologize for an ideal based on democracy rather than on commerce.

Media Armageddons and the Death of Liberal Biopolitics

Majia Holmer Nadesan

ABSTRACT

Over the last several years, Western audiences have been treated to a steady stream of post-apocalyptic disaster films. In this chapter, Majia Nadesan discusses *The Road*, *The Book of Eli*, and *9*, arguing that these films can be distinguished thematically from the more general disaster genre by their exclusive focus on post-disaster survival and their invocations of cannibalism. Significantly, she connects the emphases on post-apocalyptic survival and cannibalism to the profound social dislocations experienced by US citizens in the wake of the financial crisis. The chapter contends that thematic elements of the films are metaphors for the ascendancy of a form of financial capitalism that dispenses with labor-based suppositions of value. Nadesan contends that financial capitalism has no interest in Western, liberal biopolitics, and that the current slate of post-apocalyptic disaster films is a cultural barometer of the malaise experienced by newly expendable populations, increasingly confronted with their excess in relation to post-disaster capitalism.

Introduction

Disaster films emphasizing post-apocalyptic landscapes dominate the recent cinematic imagination. Public anxieties surrounding the fear of terrorist attacks, global

warming, flu pandemics, and fiscal crises are no doubt channeled into these films. Yet, what is unique about the contemporary disaster film is its tendency to emphasize post-disaster survival, rather than exploiting audiences' vicarious enjoyment of apocalyptic spectacle. This chapter argues that the cinematic dwelling within post-apocalyptic landscapes, particularly cannibalistic dwelling, reflects a pervasive but anonymous sense of dislocation stemming from what will be theorized as the death throes of liberal biopolitics. Liberal biopolitics, born in the eighteenth century, is quickly eroding as the population is stripped of value within new calculi for evaluating the wealth of nations. Domestic populations within the United States sense this erosion of their value and significance and therefore can identify with cinematic survivors' efforts to maintain identity and dignity in post-collapse environments devoid of basic principles of sociality. However, the cinematic obfuscation of the forces of collapse may expedite the death of liberal biopolitics by undermining the forms of concerted and directed activism necessary for resisting the onslaught of cannibalizing capitalism. The chapter begins by describing recent disaster films and then moves to explore how disaster films allude to the death of biopolitics.

Disaster Films

Disaster is a familiar theme within Hollywood productions. Maurice Yacowar (2003) traces the earliest disaster films to turn-of-the-twentieth-century productions, such as Méliès's *Collision and Shipwreck at Sea* (1898) and *The Catastrophe of the Balloon* (1902). Early disaster films articulated a thematic device that would be replicated across a century of subsequent films in the genre: the eruption of death within scenes of normality (Yacowar, 2003). In 1965, Susan Sontag described stereotyped features of disasters in science fiction films in her now classic essay, "The Imagination of Disaster." Sontag observed that disaster as fantasy "releases one from normal obligations" while often conveying simplistic moralities that encourage audiences to discharge "righteous bellicosity" (p. 45). Yet, also lurking in science fiction disaster films, Sontag remarked, are the "deepest anxieties about contemporary existence" (p. 47). These anxieties include the "very real trauma of the Bomb" as well as more generalized fears of "universal mutilation and even annihilation" (p. 47).

Although specters of death and annihilation commonly haunt science fiction disaster films, mise-en-scène features are shaped by extant cultural identities and preoccupations. Stephen Kean's *Disaster Movies: The Cinema of Catastrophe* (2006) offers readers insight into transmutations in cinematic themes and devices since the 1970s. Kean observes that 1990s-era disaster films relied on repetitions of a relatively narrow range of destructive events and scenes, as illustrated by the meteor impacts featured in *Deep Impact* (1998) and *Armageddon* (1998). These two films, like similar films of the period, focus on the events prior to, and during, disasters. Disaster presents a spectacle of enjoyment for audiences. However, post-September 11 disaster films

were marked by a new sensitivity, leading usually (but not always) to more muted representations of cinematic disasters.

More recently, disaster films released in 2009 and 2010 offer an interesting twist. As John Jurgensen and Jamin Brophy-Warren (2009) write in their *Wall Street Journal* review, "The new wave of disaster movies and TV shows isn't about staving off the apocalypse. It's what happens afterwards that counts." Recent films that explore survival after a natural or human-induced apocalypse include *Carriers* (2009), *Children of Men* (2006), *I Am Legend* (2007), *Wall-E* (2008), *28 Days Later* (2002), *Doomsday* (2008), *9* (2009), *The Road* (2009), and *The Book of Eli* (2010), among others. These films are to be distinguished from earlier apocalyptic films that address efforts to cope with anticipated disasters, halt anticipated disasters, or that sensationalize the disaster itself (e.g., *2012*, out in 2009).

The last four of the films mentioned – *Doomsday*, *9*, *The Road*, and *The Book of Eli* – are distinctive for their emphasis on cannibalism. Cannibalism is not unusual in films (e.g., Ruggero Deodato's 1980 *Cannibal Holocaust*), particularly in survival films (e.g., *Alive*, 1993), but the combined synthesis of post-apocalyptic survival and cannibalism is relatively unique. When it does occur, this synthesis tends to involve zombie cannibals (e.g., *Omega Man*, 1971; *World War Z*, 2006; *I Am Legend*, 2007; *The Crazies*, 2010). Cannibalism by fully human (i.e., non-zombified), post-apocalyptic survivors in cinema is rare. Three notable exceptions include *Soylent Green* (1973), examining a dystopic, overpopulated future; *A Boy and His Dog* (1978), a film that implicates cannibalism by a bureaucratized and totalitarian post-apocalyptic society; and *The Road Warrior* (1981), which features post-apocalyptic Australia. These three films were released within the culturally pessimistic zeitgeist of the late 1970s and early 1980s, which resulted in a number of dark, neo-noir films. Since that time, post-apocalyptic cannibalism has not appealed to Hollywood, perhaps being perceived as too risky, although a number of novels have explored this theme, notably *Farnham's Freehold* (Heinlein, 2011) and, most recently, *One Second After* (Forstchen, 2009).

However, the current cultural pessimism that is spreading across the United States has enabled the return of dark, mainstream films (see Pew Research Center, 2010). This chapter will focus on the three recent US films that address survival and (non-zombie) cannibalism in post-apocalyptic worlds.¹ The analysis argues that a change in cultural zeitgeist, rooted in the ongoing collapse of liberal biopolitics, has affected this shift in Hollywood sentiments. Support for this argument is found in the films' latent cultural significations, particularly with respect to featured thematic elements including devastated urban landscapes and debased sociality. The films, it is argued, essentially represent hauntings from an anticipated future that stem from the collapse of Western biopolitics. Each of these films will be introduced before explaining theoretically what is meant by the "death of liberal biopolitics."

The Road, directed by John Hillcoat, is based on a 2006 novel by Cormac McCarthy, adapted by writer Joe Penhall. Director Hillcoat pressed McCarthy to explain the nature of the disaster that leaves a father and his son adrift in a dead world devoid of plants, animals, and human civilization (Jurgensen & Brophy-Warren, 2009).

McCarthy reportedly responded that “it didn’t matter whether it was nuclear war or mini volcanoes or a comet” (cited in Jurgensen & Brophy-Warren, 2009). What matters in the film is the struggle for survival and dignity in a collapsed world. The father and son featured in the film navigate devastated landscapes in search of food and hope, all the while struggling to avoid other survivors who have turned to cannibalism. One of the most disturbing scenes in the film focuses on the cannibals’ “meat-locker” of starved, naked, suffering humans. When filming *The Road*, Hillcoat relied upon real disaster footage of New Orleans after Hurricane Katrina, the World Trade Center on September 11, 2001, Mt. St. Helens after its explosion, and abandoned industrial areas in Pennsylvania.

The second film to be discussed here, *The Book of Eli* directed by Albert and Allen Hughes, with Gary Whitta as screenwriter, takes place in a post-apocalypse environment 30 years after some final war. As with *The Road*, survivors struggle within ruins to find food and water. Whereas *The Road* is filmed primarily in unremitting gray, *The Book of Eli* is cast in washed-out dusty browns. What the two films share are cannibalistic survivors who signify the utter collapse of civilization. However, whereas *The Road* offers no hope for the reclamation of humanity, *The Book of Eli* suggests this possibility in the form of a Bible carried by the film’s main protagonist. Yet, the Bible is an uncertain signifier in the sense that the film explores its instrumentalization by fascist forces. In the end, *The Book of Eli* sacrifices the savior whose corporeality gives expression to the Word of the Bible. Once codified and bound, this Word is contained on a bookshelf in a hidden enclave of learning. It is shelved, and perhaps forgotten, next to the Torah and the Qu’ran.

The final film addressed here is *9*, an animated production by Burton, Bekmambetov, and Lemley (2009), directed by Shane Acker, with the screenplay written by Pamela Pettler. *9* features no humans at all in its blighted, post-apocalyptic landscape. All that remains of agency are mechanical dolls and the carnivorous machines that prey upon them. Using flashbacks, *9* explains the devastation by drawing upon the classical dialectic monster of the machine that turns against its maker. In this case, the machine, which was originally intended for productive use, was appropriated by the military for the purpose of warfare. The machine’s inventor subsequently created the mechanical dolls, within which he invested slices of his soul. These animated dolls struggle with one another over how to survive and how to evade the soul-consuming, predatory machines. When making the film, *9*’s director Shane Acker and his crew visited Los Angeles scrap yards where they found interesting junk, which they then assembled into prototypes for the animated mechanical dolls. In contrast, the carnivorous and more high-tech-looking machines threatening the dolls were simply fabricated in computer animation (Trimble, 2009). The characters in *9* are not properly human but arguably signify human cannibalism since they are human externalizations (i.e., machines) that prey upon human externalizations (dolls) invested with a human soul.

Despite differences in mise-en-scène elements, all three films examined in this analysis share a common focus on the collapse of civilization, defined in relation to

liberal, democratic principles of government. The remaining populations in *The Book of Eli* and *The Road* have lost organizing principles of social existence other than brute and corporeal power. Population is not a source of fecund energies; rather, population is the basis for ruthless competition. No social contract exists; sociality is reduced to allegiances of fealty to predatory powers. The father–son relationship dramatized in *The Road* serves only to remind audiences of all that has been lost from the world. In *The Book of Eli*, master signifiers such as the Bible oscillate between meanings, at times iconic of unleashed fascist power, while at other times iconic of law and order. 9 alone dramatizes friendships, but does so in the context of internal intrigue and despotism born of desperation.

The three films' emphasis on post-apocalyptic survival causes futures to recede, as well as the traumatic kernels of the past events that precipitated collapse. None of the films offers a happy Hollywood ending. Instead, they all dwell upon the struggle for sustenance and some basic level of security in devastated landscapes. The role cannibalistic violence plays in these films is important. Cannibalism is a direct threat in *The Road*. Predatory violence by machine against machine dominates 9. Cannibalism, fascist power, and cruelty are found in *The Book of Eli*. Of course, violence in all of its forms pervades Hollywood productions. Yet, there is something distinctive about the violence in these post-apocalyptic films. Violence is not ideologically driven or fetishized, nor is it linked to consciousness-altering madness (as with zombies), but it is driven by depravity born of desperation, as in *The Road* and *The Book of Eli*, or by the utter mindlessness found in 9's predatory creatures.

The stories told in a society always reflect aspirations and anxieties, hopes and fears. What anxieties and cultural fears infuse the thematic elements of these post-apocalyptic, blasted landscapes and desperate, hopeless survivors? Moreover, how do the tropes, plots, and landscapes of today's films diverge from the history of disaster films? The films described in this section, *The Road*, 9, and *The Book of Eli*, differ from the disaster film genre by their relatively small casts and apparently simple themes. Unlike previous films in this genre, these films de-emphasize the disaster as they are set years after the cataclysm, which is only alluded to, rather than sensationalized. Additionally, the main threats posed to the survivors of the three disaster films examined in this analysis are scarcity (except in 9) and predatory, cannibalistic violence. It is my argument that these two threats serve as sites of condensation for popular anxieties surrounding fundamental dislocations in liberalism as a politico-economic ideology and as a way of life.

Liberalism, the Labor Theory of Value, and the Wealth of Nations

This chapter argues that thematic elements of current disaster films point to a deep sense of trepidation in the US cultural imagination. The zeitgeist has shifted away

from optimism for the future, as the foundations of society are perceived to be in jeopardy. The analysis offered by this chapter extends beyond surface expressions of popular dissatisfaction to address a problematic trend within Western liberalism that, arguably, is becoming increasingly evident to the US populace. That trend is the *growing irrelevance of the populace for the creation of value*. This chapter argues that a nagging sense of the populace's irrelevance is percolating in the collective cinematic imagination of the nation. However, the cinematic imagination functions akin to a collective unconscious: cinematic displacement and condensation mask traumatic kernels of understanding. The cinematic dream-work weaves potent symbols of anxiety and dislocation into a coherent narrative that ultimately obscures the symbols' relations to the crisis of liberal capitalism. This section explores the crisis of liberal capitalism that has dislocated the populace as the source of value. The devaluation of the US population within capitalist calculi of value is leading to what I describe as the death of liberal biopolitics. This analysis will be linked to the films in the subsequent section.

This section is organized by a central contention: it is my argument that liberal biopolitics is tied implicitly to the capitalist labor theory of value. Consequently, the growing irrelevance of US labor (and aggregate consumption) today for the accumulation of capitalist value negates justification for liberal biopolitics within the nation. In order to unpack this argument, it is helpful to return to the birth of biopolitics as it emerged with Western capitalism and liberalism in the eighteenth century.

Western capitalism emerged in tandem with Western liberalism. Liberalism, as expressed in the founding documents of Adam Smith and John Locke, is a form of political rule that posits and advocates limits to sovereign control over the economy and individuals. Liberalism substitutes the corporeal, centered power of the sovereign over the individual and his/her market transactions with "natural" laws and disciplines. As explained by Michel Foucault in *The Birth of Biopolitics*, market veridiction – e.g., in the form of Smith's guiding hand – was the regime of truth that adjudicated the correctness of governmental practices under liberalism. Accordingly, liberalism is essentially "indexed to the problem of the market and market veridiction" (Foucault, 2008, p. 56). Markets purportedly permit "natural" or spontaneous mechanisms to set "natural," "good," or "normal" prices (p. 31). Within classical liberal political economy, market prices were believed to have a certain, almost meta-physical, relationship to the work performed to produce market commodities. Accordingly, in 1776 Adam Smith argued in *The Wealth of Nations*:

The value of any commodity, therefore, to the person who possesses it, and who means not to use or consume it himself, but to exchange it for other commodities, is equal to the quantity of labour which it enables him to purchase or command. Labour, therefore, is the real measure of the *exchangeable value* of all commodities. (2003, p. 43, emphasis added)

In *The Economics* (1857–1867), Marx (2000) commented upon the importance of Adam Smith in defining labor, in its abstracted form, as the source of wealth production,

particularly in exchange relations. For classical liberalism, *labor power is the ultimate source of exchange value*; that is, it is the natural and foundational truth of the market. The capitalists' accumulation of surplus value derives from the objectification of the wage earners' "living labour" (Marx, 2000, p. 400). Wages paid to labor, from the classical perspective, derive directly from the workers' power to command wage levels. Disutility is the term used to describe the condition where low wages disincentivize work. Classical economists believe that wages settle just above disutility (Keynes, 1936).

The market's capacity to adjudicate truth presupposed a special market agent capable of assessing information rationally when selling work or when involved in other types of commodity transactions. Thus, Adam Smith argued that society is fundamentally composed of "commercial" actors: "Every man thus lives by exchanging, or becomes in some measure a merchant, and the society itself grows to be what is properly a commercial society" (2003, p. 33). *Homo economicus* is the rational commercial agent of exchange. His (gendered) comparative advantage is embodied in his labor capacity and/or in the labor "stored" in products or coinage he controls. The imagined transparency and competitiveness of this idealized marketplace of labor and goods allows for the most efficient exchange and distribution of societal goods possible.

Laissez-faire is the principle of government that is viewed as allowing the labor and commodity markets to operate efficiently, according to their natural or spontaneous competitive mechanisms (see Riskin, 2003, p. 47). The moral component of laissez-faire derived from Adam Smith's belief that the individual's rational, self-interested market behavior produced the most positive collective outcomes for society, thereby aligning private market interests with public advantage (Smith, 2003, p. 572). The underpinnings of classical liberalism, including laissez-faire and *homo economicus*, prevailed throughout the nineteenth century despite evidence of the market's failure to distribute resources efficiently or rationally through much of that century, as pointed out so clearly by Karl Marx (2000).

However, laissez-faire did not result in the abdication of state power. Through the vector of a secularized pastoral power, the state assumed greater interest in, and responsibility for, the biovitalities of the population, forging biopolitics. According to Foucault, biopolitics emerged under state mercantilism through the technology of political statistics and the assemblage of police (Foucault, 2007, pp. 278, 315). Biopolitics, a form of power that addresses the biovitalities of human bodies, involved "distributing the living in the domain of value and utility" (Foucault, 1990, p. 144). Biopolitics inherited from the police the objective of ensuring the health of the population and preventing idleness (Foucault, 2007, p. 325). Biopolitics, aimed at the population, was complemented by anatomico-power, which operated on the living bodies of workers and soldiers in order to govern and extract value from their labor power (Foucault, 1990). Although early biopolitical endeavors, such as the nineteenth-century sanitation movement, involved a convergence of private and state authorities, biopolitical practices eventually were adopted as technologies of the self,

as individuals endeavored to master hygienic practices of self-government. Still, biopolitics remained essentially a responsibility of state government as the health and vitality of populations were linked to state security and economic prosperity (Nadesan, 2008). Foucault therefore claimed that under the evolving liberal state, the population “will appear above all as the final end of government” with the end being aimed at increasing the population’s “wealth, its longevity, and its health” (2007, p. 105).

The historical relations between biopolitics and the demands of capitalist accumulation are fraught with tensions and the former is not reducible to the imperatives of the latter (see Nadesan, 2008). That being said, biopolitics finds its justification in enabling the subject of liberalism, *homo economicus*, while fostering the economic and political security of the nation. Indeed, Foucault (2007) stressed that biopolitics must be understood “on the basis of a theme developed in the seventeenth century: the management of state forces” (p. 367). It is not surprising therefore that overt tensions between (1) market logics of extraction and accumulation and (2) the health of the population (the totality of *homo economicus*) have produced great legislative and judicial conflicts for liberal Western states that declare democracy while encoding the logics of property within their democratic documents (see Beard, 1913; Hardt & Negri, 2009).

The great European and US depressions of the 1930s pitted the vitalities of populations against the liberal freedoms of the market while also demonstrating how laissez-faire market failures problematize through fascism the very idea of the liberal state. Recognizing that laissez-faire capitalism tends to result in overproduction (and underconsumption), John M. Keynes sought to temper the business cycle by expanding the state’s role in stabilizing demand, through expansion of the public sector and by regulating employment. Keynes’s observations that the populace could experience “involuntary unemployment” and that markets often exhibited irrationality problematized laissez-faire assumptions (1936, p. 10). Keynes particularly emphasized the dangers of speculation, which had contributed to the Great Depression:

Speculators may do no harm as bubbles on a steady stream of enterprise. But the position is serious when enterprise becomes the bubble on a whirlpool of speculation. When the capital development of a country becomes a by-product of the activities of a casino, the job is likely to be ill done. (1936, p. 132)

Keynesian economics employed the state to promote full employment and regulate speculation, while still encouraging a capitalist economy and market system. In the United States, military Keynesianism contributed to union-based manufacturing while expanded social welfare and education spending delivered improved living standards for much of the populace.

Liberal biopolitics thus expanded significantly in the post-World War II era. The intense study and promotion of physical and mental “health” became a defining feature of the post-World War II security state in the United States (and Western Europe) through programs such as free lunch, expanded welfare, social security, and

services for the disabled. These programs were infused with power relations and produced resistance from populations subjected to them, especially in the 1960s and 1970s; however, they did in many ways prioritize national vitality, construed in relation to the populace's economic productivity (e.g., consider social security, free milk and lunch programs, head-start, welfare, etc.).

Classical laissez-faire was not, however, completely abandoned in the post-World War II era. Austrian economists such as Friedrich von Hayek and Ludwig von Mises sought to free economic theory and practice from Keynesian constraints and influence and to liberate the populace from "dependence"-fostering social welfare programs. Yet, it was the Chicago School "neoliberal" economists whose ideas were most fully implemented, first in trial nations such as Chile and Mexico through the leverage of global governance institutions such as the International Monetary Fund (IMF) and World Bank. The World Trade Organization, which replaced the post-World War II General Agreement on Tariffs and Trade in 1995, also assumed a role in propagating neoliberal policies by dictating the elimination of Keynesian tariffs and subsidies. The emphasis on export-oriented production in the developing world, coupled with the liberalization of trade and finance, presented economic opportunities to corporations based in the developed world seeking to escape the (perceived) onerous (Keynesian) labor, tax, and environmental regulations of their host nations. Automation and globalization enhanced corporate earnings as the labor disutility rate sank ever lower; however, the most lucrative technology for sheer accumulation involved financial speculation, rather than production activities.

Indeed, within neoliberal states such as the United States and the United Kingdom, the intensification of capital accumulation in the 1980s through today derived less from the enhancement of labor's productive capacities and the sinking of the disutility rate than from the growth of financialization. Financialization occurred within the United States as financial motives, institutions, and elites became increasingly important in shaping the economy in response to the decline in profit margins in manufacturing (see Foster & Magdoff, 2009; Vasudevan, 2008). US banks grew to dominate their domestic economies: by 2010, six US banks held assets in excess of 63% of the US gross domestic (Moyers, 2010). Moreover, innovative financial instruments such as derivatives, collateralized debt obligations, and credit default swaps enabled the financial investment banks and commercial banks (after repeal of the Glass-Steagall Act) to accumulate wealth outside of the circuits of commodity production (LiPuma & Lee, 2004). Bryan, Martin, and Rafferty (2009) claim there is no direct historical equivalent for this new form of financialization, not simply because of the size of financial institutions, but also because securitization and financial derivatives "*are transforming capital accumulation*" in ways unimaginable by Marx and the classical economists (my italics, p. 459).² Contemporary financialization requires little labor to produce value (see Nadesan, in press).

Financialization in the United States has not only driven out most manufacturing, but it has also shaped the operations of almost every other industry by encouraging monopolization, lean production, and outsourcing (see Lynn, 2010; Rasmus, 2010).

US manufacturers had little incentive to invest in domestic labor, or even to modernize their manufacturing capacities at home, when higher profits could be achieved by offshoring production or by downsizing manufacturing by investing instead in financial products and services (see Roberts, 2010). Indeed, over the last 30 years, US and UK corporations that formerly made things – such as autos and lightbulbs – found newly established financial services divisions to reap greater profits, as illustrated (prior to the recession) by the financial services arms of both General Electric and General Motors. Thus, financial logics replaced production ones even within manufacturing (Phillips, 2008).

New vocabularies and metrics circulated within the United States and United Kingdom to rationalize the evolving financialized economies. Keynes's disparaging representation of the financial market as a casino was substituted by the neoliberal "efficient market" theory, which presumes market transparency and rationality (Krugman, 2009). Metrics of national well-being, such as unemployment or wage increases, were de-emphasized by the new authorities of "political monetarism," which focused only on the stock of money supply while ignoring all other macroeconomic statistics, including unemployment statistics (DeLong, 1999). Thus, neoliberal, supply-side vocabularies and metrics pushed by the Chicago School economists replaced the post-World War II Keynesian emphasis on aggregate consumer demand.

The Keynesian link between wages and aggregate consumption was broken, rendering the earning potential of the populace less relevant to financiers and policymakers alike. Low interest rates encouraged by monetary economists enabled debt-based household consumption in a context of stagnating wages. Greater concentrations of wealth at the top enabled huge luxury expenditures by the wealthiest 10% of the populace. Average workers' wage levels were increasingly perceived as irrelevant to economic growth and wealth accumulation by Wall Street and policymakers alike.

Simultaneously, corporate stock prices became less dependent upon consumer expenditures. Outsourcing and automation allowed corporate assets to grow (by squeezing labor costs) even if consumption remained constant. Additionally, pension programs and 401ks directed retirement funds toward inflating equities, which promised higher returns than the more traditional safety of lower-interest-earning bonds (Joint Economic Committee, 2000). Finally, as mentioned above, corporations expanded their financial services and partnerships, producing annuity-like steady streams of interest from consumer debt.

These transformations achieved through the neoliberal financialization of the US economy enriched Wall Street banks and investment firms, hedge funds, and the wealthiest US citizens. Contributing to their capacities to acquire wealth outside of production was the expansion of derivatives (LiPuma & Lee, 2004) and new computer-based trading technologies (see Nadesan, in press). Financial traders found that rising stock prices were no longer necessary for financializing corporations or traders to accumulate profits. With the advent of high-frequency trading, market volatility itself produced speculative opportunities to high-frequency traders (see Nadesan, in

press). Speculation embraced losses as well as gains as the novel insurance of “credit default swaps” ensured profitability on the riskiest of investments.

The decreased relevance of US labor impacted wage levels, household income, and local communities’ tax base. Citizens’ earning capacities deflated with fewer union job opportunities and stagnating wages. Simultaneously, public investments in educational and manufacturing infrastructures collapsed in all but the most privileged of areas. Household indebtedness grew.

Speculative or rentier, debt-based capitalism expanded throughout US society as consumer debt was encouraged by the financial services industry (see Phillips, 2008). Debt was securitized into financial instruments such as bonds, derivatives, and collateralized debt obligations that could be sold to unwary investors (see Pollin, 2007). The originate-to-distribute lending model that permeated nearly all forms of credit instruments made debt a highly profitable commodity while distributing “risk” internationally as investors around the world purchased bonds and derivatives created out of pooled debt.

The reinvention of laissez-faire under neoliberalism offered another tempting technology for capital accumulation rooted in the predation upon, and privatization of, Keynesian (social and military) security apparatuses. David Harvey (2005) described a “neoliberal state” whose mission is to “facilitate conditions for profitable capital accumulation on the part of both domestic and foreign capital” (p. 7). In 2008, James Galbraith defined a “predator state” as “a coalition of relentless opponents of the regulatory framework on which public purpose depends, with enterprises whose major lines of business compete with or encroach on the principal public functions of the enduring New Deal” (p. 131). Predatory corporations dictate and “poach” upon public purpose and have no loyalties for nations or populations (p. 131).

The neoliberal, predatory state that emerges in the descriptions provided by Harvey and Galbraith diverges from the frozen, idealized descriptions of the liberal state provided by founding neoliberal thinkers such as Friedrich von Hayek (1991) and Milton Friedman (1962). Yet, current US bailout policies and programs point to a predatory neoliberal state whose mission it is to resolve and remediate (without altering) the problems of governance stemming from neoliberal deregulation, privatization, and financialization. Neoliberal economists have responded to this type of criticism by defending the natural superiority of “efficient markets” and “competitive advantage.” Neoliberal think tanks promoted the market-friendly, debt-based technology of individual micro-enterprise as the solution for growing structural unemployment (Karoly, 2007). From the perspective of neoliberal authorities, what mattered was steady expansion of the nation’s gross domestic product (GDP) and credit, not job creation. Government policy obligingly aimed primarily at ensuring steady expansion of the monetary supply (Krugman, 2009). Dissent was subdued by the combination of steady growth and low inflation, despite growing evidence of aggregate demand-dampening economic inequality.

A 2005 Citigroup document highlighted in Michael Moore’s (2009) film, *Capitalism: A Love Story*, illustrates the increasing irrelevance of the populace, in terms of both

their productive *and* consumptive capacities. The October 16, 2005, document, “Equity Strategy: Plutonomy: Buying Luxury, Explaining Global Imbalances,” describes a world “dividing into two blocs – the plutonomies, where economic growth is powered by and largely consumed by the wealthy few, and the rest” (p. 1). The United States is a “key” plutonomy characterized by

disruptive technology-driven productivity gains, creative financial innovation, capitalist-friendly cooperative governments, an international dimension of immigrants and overseas conquests invigorating wealth creation, the rule of law, and patenting inventions. (pp. 1–2)

The productive and consumptive capabilities of populaces within plutonomies cede in significance to the wealth accumulated by the few through technology that replaces workers, financial “innovations” capable of accumulating wealth outside of production (e.g., through securities transactions), and through overseas colonial exploitation of resources and labor.

The populace’s loss of value within economic calculi is highlighted in an article posted May 18, 2010, at the popular web page, the *Economic Collapse* blog. The article, titled “The Declining Value of Work,” authored by Michael Snyder, argues: “Thanks to rapid advances in technology, and thanks to the globalization of the work force, the labor of American workers is rapidly losing value.” In contrast to disposable workers, corporations continue to accumulate value by leveraging their monopolization over required commodities (e.g., food), by deriving value from overseas labor, and most significantly, from financial speculation.

The great financial crisis that began in the winter of 2007 shook neoliberal foundations and accelerated the problem of structural unemployment that had been developing since the dot.com collapse. Suddenly, deregulation and speculation were out of vogue among populist pundits. The past great moderation was reinterpreted as a bubble. Even mainstream commentators began questioning neoliberal, *laissez-faire* logics, including the ontological status of *homo economicus* (see Roubini, 2009; Thoma, 2009).

Members of the populist, libertarian right have joined the populist left in their criticism of the financialization of the economy and the growing power of the military–industrial complex. The libertarian right’s suspicion of the state extends beyond liberal Keynesian thought promoted by figures such as James Galbraith, but converges with the left-of-center critique of the role of financialization in eroding the US industrial base and the growing power of what the libertarians term “crony capitalism.” For instance, libertarian Alex Jones of *Prison Planet* offers a conspiracy narrative of an elite group of financiers striving to create a new world order. Libertarian-inclined financial web pages decry the death of the republic, debt peonage, and deindustrialization, even while they reject social welfare redistributive apparatuses and promote a nostalgic and phantasmic vision of the nineteenth-century United States where individual labor and enterprise resulted in success.

Libertarian and leftist narratives of the economic and social changes wrought by neoliberalism adopt distinct vocabularies and promote different solutions to the financial crisis that began in December of 2007. Despite these differences, both narratives explain the transformation of capital accumulation in relation to the ascendancy of financialization, deindustrialization, and the growth of monopolistic and predatory capitalist interests whose lack of national identification enables them to operate globally and largely impervious to nation-states' regulatory apparatuses. Both groups share a disturbing sentiment that the population no longer serves as the primary basis for capital accumulation, nor for the determination of national wealth. Both groups share Max Keiser's concerns that the United States is being transformed into a "neo-feudal gulag economy" (Keiser, 2010).

Liberal Dreams, Liberal Nightmares

The ascendancy of neoliberal logics of financialization and the growth of predatory capitalism have wrought profound material changes to the economic configurations and social institutions that formerly characterized the United States of the mid- to late twentieth century. Together, these forces have dislocated the foundations of liberal biopolitical apparatuses. How might this dislocation, and the anxieties that it induces among those who must navigate its precarious material conditions, manifest in the realm of cultural production? This section explores how cinematic themes and tropes in *The Road*, *9*, and *The Book of Eli* register and refer indirectly to the anxieties and fears of a dispossessed populace.

The Ambiguity of Collapse

The first theme shared by all three films is the ambiguity surrounding the source of collapse. All three of the films' narratives begin in a post-collapse landscape. *9* and *The Book of Eli* offer oblique references to devastating wars responsible for the collapse, but the point of, and parties to, these wars are obscure. *The Road* offers audiences few insights into the nature of the disaster. The thematic ambiguity surrounding the sources of collapse resonates with the uncertainty US citizens feel about the causes of the financial crisis that is currently wreaking havoc upon the nation. The nature and operations of the securitized bonds, credit default swaps, and derivatives held responsible for the financial crash are difficult to understand; indeed, they were designed to be unintelligible to all but the people who designed them (Taibbi, 2009a).

The financial crisis wrecked the economy – as evidenced by massive job losses, foreclosures, personal bankruptcies, and mounting hunger – without bombs, invasions, or civil insurrections. Growing unemployment headlines in the media beginning in 2009 were one of the most visible symptoms of decline. Drawing on

reports by economists, the press began reporting a sharp decline in the civilian workforce (Evans-Pritchard, 2010).³

Declining income produced mass personal bankruptcies, which reached records not seen since immediately prior to the tightening of bankruptcy standards in October 2005 (Wilson, 2010). Perhaps the clearest symptoms of the recession were the growing home delinquencies and foreclosures. TransUnion, a financial and credit analysis organization, found national mortgage delinquencies jumped over 10% at the close of 2009 (TransUnion, 2010). TransUnion observed that the final quarter of 2009 constituted the twelfth consecutive quarter of rising delinquencies and anticipated that 2010 would lead to even greater delinquency rates. By May 2010, 14% of US mortgages were over 30 days delinquent or in some state of foreclosure (Hoak, 2010). The home foreclosures resulting from these delinquencies produced media spectacles of tent cities, media reports of overwhelmed homeless shelters, and a general increase in visible rates of homelessness on the nation's streets.

The spectacles of empty, foreclosed homes, empty strip malls, and abandoned real estate developments, particularly in the West and Southwest, resonated with disaster films' depictions of urban collapse and devastation. Media accounts of squatters' occupation of empty properties paralleled the cinematic depictions of survivors seeking shelter in the dilapidated, empty buildings of post-collapse societies. Even in affluent neighborhoods, the decay of foreclosed homes was detectable. Empty, declining buildings and untended gardens were specters of collapse that could not help but contribute to a climate of insecurity and generalized anxiety. The cinematic representations of such contexts eerily aligned with the aftermaths of the housing bubble.

Confusion reigned in the real world as it did in the cinematic universe of post-collapse societies. Collapse in the real world seemed inexplicable, but also irrefutable, as reports of cliff-diving tax receipts and municipal and state fiscal crises dominated headlines. Public employees – those Keynesian defenses against collapsing private demand – received pink slips daily, a phenomenon figuring prominently in media newscasts. The twentieth-century security state shuddered as states and municipal entities cut social and public safety services. Food insecurity, that specter of need supposedly vanquished by the security state, emerged once again, a shadow of the terrifying starvation conditions represented in post-collapse cinema. By 2010, one in eight US citizens relied on food stamps (Abbott & Hill, 2010). Food banks were stretched to the limit and anticipated shortages with ongoing demand increases. Public schools witnessed greater demands for free lunches, straining school lunch programs nationally (Bjerga, 2010). Recession gardens captured the public imagination, although much of the populace no longer had the skills and know-how to grow produce (Sutter, 2009).

In the parallel cinematic world of post-apocalyptic disaster films, survivors live in blasted landscapes incapable of sustaining life. Production is impossible in these devastated imagined worlds. The lands are depicted as infertile, incapable of supporting plant or animal life. Homeless survivors trudge through dilapidated highways

and city streets, seeking occasional shelter from ruined buildings as they trudge forward on their respective missions: to reach the coast in *The Road*, to save an acquaintance in 9, and to reach some unknown destination in *The Book of Eli*. Survivors must rely on the detritus of former civilizations for their survival. Once again, survival is a struggle and scarcity dictates the conditions of the living.

Although US citizens did not face blasted landscapes in the wake of the financial collapse, they did increasingly confront evidence of the nation's slowly eroding infrastructures. Falling bridges, failing and vulnerable electrical grids, and polluted public waters captured media headlines. Viral epidemics such as swine flu that threatened to result from factory farming bred concern about the nation's food supplies. The film *Food Inc.* (Robert Kenner, 2008) sensationalized the health perils of the pesticide-ridden, petro-dependent global food-supply chain. Peak oil loomed as the US military warned of oil shortages by 2015 (Macalister, 2010). Closely following, mass-mediated environmental disasters – including Hurricane Katrina, the Asian tsunami that devastated parts of Indonesia and India, the Haitian earthquake, the BP oil spill in the Gulf of Mexico, and the earthquake and tsunami that leveled parts of northern Japan and left the country with a major nuclear catastrophe – dramatized the unregulated forces capable of felling societies and the impotence of governments. The twentieth-century belief that rational science had tamed the uncontrollable chaotic forces of nature was revealed as false.

Simultaneously, the natural world appeared increasingly “at risk” from the seemingly suffocating and life-denying activities of civilization. An endless stream of ecological problems seemed to take on increasingly catastrophic proportions: desertification caused by agriculture eroding arable land, clean water sources degrading and in decline, and pollution threatening the biosphere. The United Nations warned that the world's ecosystems were at risk of “rapid degradation and collapse” (Knight, 2010). Oil dependency, in particular, began to be experienced as suffocating life in the spectacles of environmental destruction wrought, for example, in Canada's oil sands and within the Gulf of Mexico as a result of the oil disaster there, the scope of which was incomprehensible. What emerged was a picture of the cumulative effects of the conditions and practices of twentieth-century life as itself posing a catastrophic threat to the biosphere. Environmental threats rendered human life a threat to life itself, surplus human life seeming to choke the life of the planet. Post-apocalyptic disaster films registered this bleak vision of reality.

Cannibalism, Debt, and Vampire Squids

Life chokes life, just as debt accrued during the twentieth and early twenty-first centuries was perceived as sapping contemporary vitalities. US citizens struggled to remain solvent, as falling incomes and long-term unemployment exacerbated escalating debt levels (see, e.g., Borie-Holtz, Van Horn, & Zukin, 2010). Sovereign (i.e., government) debt ballooned as bailouts and FDIC takeovers of zombie banks and

insurance companies continued unabated. Fears of market-swallowing governments seized economic conservatives. Fears of debt peonage to ruthless corporations or foreign governments (i.e., China) took hold among liberals. The critical financial press warned of predation by the cannibalistic products of late twentieth-century financial innovations.

Rolling Stone magazine's crusading reporter Matt Taibbi reported quarterly on the excesses of US investment banks, particularly Goldman Sachs, a financial firm accused of deliberately swindling funds from clients and the US government alike (in the form of securities fraud and bailouts through AIG) (see, e.g., Taibbi, 2010b). For instance, Goldman and J. P. Morgan indebted local municipal entities and school districts by selling interest rate swaps that ended up exponentially increasing the interest rates these public entities were forced to pay on their debt, resulting in bankruptcies, raided public pensions, and/or higher local taxes (see, e.g., Taibbi, 2010a; Tavakoli, 2010). Goldman and other investment banks also sold synthetic collateralized debt obligations to public entities, which they subsequently betted against (Dugan, 2010).

The capacity for investment banks to drain public entities was not restricted to local municipalities. In February of 2010, investment banks shorted Greek bonds and used credit default swaps to bet that the nation of Greece would default on its debt. These actions caused investors to pull out of the Greek market, hampering Greece's efforts to raise capital by causing interest rates for Greek debt to skyrocket because of rising credit default rates (Schwartz & Dash, 2010). Investment banks' predation illustrated how financial profit-making that boosts national GDP can simultaneously drain national vitality by crippling public entities. In July of 2009, Taibbi aptly described Goldman Sachs as "a great vampire squid wrapped around the face of humanity, relentlessly jamming its blood funnel into anything that smells like money" (Taibbi, 2009b).

In post-apocalyptic disaster films, the metaphor for these insidious real-world forms of financial predation was cannibalism. In *The Road* and *The Book of Eli*, starved survivors lose their moral bearings and turn to human predation. In 9, a soulless, predatory machine imbibes the spirit animating the mechanical dolls who struggle for survival. Cannibalism is a means for survival at the cost of sociality, that foundational value of humanity.

Cannibalism occurs also in the popular US imagination as the state assumes control over the operations and risks of the market sector. The discourse of the autonomous and self-regulating market has been a fixture of the US cultural imagination since at least the eighteenth century. State socialism is, in the mind of the average US citizen, equivalent to state fascism. Hence, the state's acquisition of market firms is viewed as a form of threatening cannibalism, even when state control is seemingly necessitated by the systemic risks produced by an institution's insolvency. Strangely, this fear of state cannibalism seems to outweigh the fear of the vampire squid and other predatory corporations that strive to control the state in order to feed upon public largess (e.g., through regulatory capture and bailouts).

This fear of the cannibalistic state stems, no doubt, not only from the cultural fetishization of free markets but also, simultaneously, from the fear of constricting government deficits. The public has been conditioned by decades of shrill warnings from fiscal conservatives about the smothering dangers of federal deficits despite the US dollar's status as the global reserve currency. Randall Wray argues persuasively in *Understanding Modern Money* that this fear of deficits stems from a tendency to equate sovereign financials with household financials. Wray contends that this equation is not only false but dangerous, because decades of empirical analyses link federal surpluses with recessions. The sovereign, according to Wray, can create money without issuing debt, and, unlike banks, which exercise the same option, the sovereign need not back money creation with reserves of any form. Wray's account of modern money gets at the integrally socially constructed nature of value. Yet, the account of sovereign debt that circulates in business periodicals and the popular press reinforces the interpretive framework and calamitous fears of fiscal conservatives, thereby reinscribing a view of money that will lead the state to select austerity in social spending, since military spending is untouchable. Popular assumptions and government reactions to fiscal deficits increase the sense of dislocation experienced by the population.⁴

Surplus Populations

In recent disaster films, population is not a fecund source of libidinal energies. Populations primarily signify scarcity, rather than productivity. The biovitalities of the population signify only unmet needs. There is no production, only scarce consumption opportunities. The population has no value. In order to understand this devaluation of the productive capacity of the population it is helpful to return to the historical specter that haunted liberal political economy, poverty through overpopulation.

Classical liberalism viewed the population as a source of value insofar as populations adapted their numbers and characteristics in relation to the natural properties, ebbs, and cycles of the market. *Homo economicus*' prudence and moral restraint are exercised in no area as important as his/her fecundity (see Greene, 1999). Classical liberals believed that excessive population growth produces poverty by driving down wages and by creating scarcities. Unchecked poverty threatens security. Yet, the remediation of poverty through the state's redistributive efforts violates the natural operations of the market and the property rights of citizens. Thus, the classical liberal solution to the problem of poverty is found not in the state but in the dynamics of population (Bland, 1973). The population must secure itself from pauperism by controlling its fecundity in relation to the market's labor needs. In reality, starvation, disease, and war curtailed what "prudence" could not.

The Keynesian-inspired state sought to intervene in the Malthusian dynamics of population and markets by tempering market downturns and by engineering demand.

The state proactively enhanced the productive capabilities of the populace through social welfare biopolitics aimed at ensuring adequate and accessible food, education for all, and some minimum level of healthcare. Keynesian-inspired biopolitics never obliterated surplus populaces, even within “advanced” economies, but it did soften the impact of capitalism’s tendency for overproduction with vast “safety nets” such as unemployment insurance, food stamps, and jobs-training programs. The Darwinian laissez-faire market was thus tamed by a state that viewed the populace (i.e., aggregate demand) as an important foundation of national vitality.

The idea that the US population might pose problems for national vitality was perhaps first outlined in the post-World War II era by US President Richard Nixon, who introduced a “Commission on Population Growth and the American Future”:

How will we educate and employ such a large number of people? Will our transportation systems move them about as quickly and economically as necessary? How will we provide adequate health care when our population reaches 300 million? Will our political structures have to be reordered, too, when our society grows to such proportions? Many of our institutions are already under tremendous strain as they try to respond to the demands of 1969. Will they be swamped by a growing flood of people in the next thirty years? How easily can they be replaced or altered? (Quoted in Leschak, 1996, p. 82)

This Malthusian concern about population outstripping job and resource availability directly called into question the willingness or capability of the Keynesian state. Malthusian fears were fanned by this acknowledgment and by the emergence of an environmental movement that challenged the liberal premise and promise of infinite growth and expansion. The explosion of neo-noir films in the 1970s, such as *Soylent Green* and *A Boy and His Dog*, reflected growing cultural pessimism about the virtues and sustainability of the modern liberal state.

Despite the eruption of cultural angst in the 1970s, the vast majority of the US populace has long been unwilling to confront its own Malthusian anxieties because the nation’s foundational narratives deny the possibility that personal initiative might go unrewarded. In the early 1980s, Ronald Reagan and Rambo helped suppress the dystopian projections of the 1970s. Malthusian fears were contained and displaced by collective cultural fantasies that defined the poor and unemployed as Darwinian misfits, who were responsible for their plight due to their culture of poverty and lack of adaptive skills. Malthusian fears have also been projected upon foreign populations whose (purportedly) unchecked fertility is seen as threatening scarce resources. In this fashion, the Western world is absolved of blame for the pressures of overpopulation; simultaneously, the developing world is implicated in dystopic predictions of the planet as a postindustrial wasteland, characterized by heat, chronic food and energy shortages, and unchecked disease (McDougall, 2010). The US cultural imagination also displaces Malthusian fears within the iconic form of the illegal immigrant. Anti-immigrant xenophobia in states such as Arizona must be understood in relation to these suppressed and displaced Malthusian anxieties. At base, the suppressed fear

is less about illegal immigrants taking jobs desired by citizens than it is about the citizens' fear that there exist no living-wage jobs for them to take.

US news reports of growing unemployment and underemployment within the United States have ruptured precisely those fantasies that previously contained Malthusian anxieties (see, e.g., Borie-Holtz et al., 2010; Goodman, 2010; Wessel, 2010). News reports detailing the desperation of middle-class unemployed workers strike fear in the hearts of wage earners across the nation. News reports of unremitting, escalating demands upon food banks and state unemployment funds threaten the foundations of the US fantasy of universal prosperity for the prudent and well educated. News reports of strained public finances threaten the omniscience of the Keynesian state.

The emergence of public discourses that acknowledge the widespread existence of surplus populations within the United States point to, and represent a dislocation of, the (Keynesian) biopolitical regime that has prevailed since being instituted in the post-World War II environment. It is the argument of this chapter that this dislocation stems not, as capitalists would have us believe, from some intrinsic and unavoidable necessity. Rather, the argument made here is that through regulatory capture the Keynesian state is being forcibly undone by rent-seeking capitalists who no longer view the populace as relevant to the production of value. Thus, the remaining social security apparatuses – including Medicare, Social Security, and federal funds for state unemployment and disability programs – are under frontal assault while Congress contemplates corporate tax cuts and individual estate tax reductions for the richest US citizens. Today, capital has largely forsaken the labor of developed economies and, with the implosion of the debt bubble, can no longer extract ever more value in the United States through debt servitude, because of massive deleveraging and credit defaults. Consequently, biopolitics that is not tied to privatized acts of consumption among the ever-diminishing middle classes (i.e., for-profit health and wellness) loses salience within established and emerging Western plutonomies. Austerity – the death of liberal biopolitics – “solves” the fiscal challenges of sovereign entities from the point of view of a form of capitalism that has forsaken labor. Within the United States, therefore, states and local governments are being forced to cut services to the poor, the disabled, and the young, precipitating a crisis in liberal biopolitics as programs aimed at enhancing education, health, and well-being are axed. The intensification of human labor is sacrificed on the altar of rentier capitalism.

It is noteworthy that two recent, popularly oriented books make similar arguments. The first is Arianna Huffington's *Third World America* (2010), which provides a glossy analysis of the demise of the American dream. The second is Jacob Hacker and Paul Pierson's (2010) *Winner-Take-All Politics: How Washington Made the Rich Richer – and Turned its Back on the Middle Class*, which examines the public policies and programs that allowed the rich to cannibalize the rest. These texts, I believe, illustrate the populist coming-to-consciousness of a new zeitgeist of dispossession and marginalization that is echoed and amplified in recent post-apocalyptic disaster films.

Conclusion

The stories told by a society reflect fears, anxieties, and nightmares in addition to aspirations and idealizations. Disaster and apocalyptic films in general allude to, and project, societal tensions and anxieties. This chapter has argued that early twenty-first-century films like *9*, *The Book of Eli*, and *The Road* inscribe lurking, but inchoate, suspicion that the general populace of the United States no longer is perceived as vital to, or for, the production of wealth by policymakers and societal elites. A new zeitgeist is birthed within which the population of advanced Western economies ceases to calculate as a nexus of value. The telos of liberal biopolitics ceases to exist in nations that have forsaken the labor theory of value.

The labor theory of value was a central tenet of capitalist logics for almost two hundred years within Western societies. However, the economic stagnation of advanced industrial societies spurred expansion of a form of rentier capitalism (Pollin, 2007) that enabled unprecedented levels of capital accumulation by wealthy elites from a relatively smaller pool of debt incurred by a general populace facing declining and/or stagnating wage levels. Financialization, as this form of rentier capitalism has been dubbed, produced vast speculative, debt-based bubbles that masked growing economic inequality and declining economic opportunities for at least two decades, particularly within the United Kingdom and the United States. The collapse of this bubble has led to the further impoverishment of the working class and has compromised the employment and consumption of an increasingly tenuous, fragile middle class. The incredible and unprecedented transfer of wealth that resulted from the financial crisis when governments assumed the losses of the corporate sector has further impoverished a populace faced with fiscal conservatives' demands for austerity targeting government-supported education, health, and retirement programs. To the degree that they are successful, such calls for austerity signify the state's abdication of the telos of population, the abdication of liberal biopolitics.

Structural unemployment and underemployment face a populace who can no longer rely on Keynesian demand engineering programs, ranging from education to social safety nets. The hollowing out of the manufacturing sector and the collapse of the finance/real estate/insurance economy (FIRE) have produced an epochal deleveraging that threatens to persist for years. What remains of liberal biopolitics is attacked by elites and righteous deficit hawks who see little to no value in the populace. The population's ever-decreasing consumptive powers mean that the logic of aggregate demand ceases to resonate. The environmental benefits of declining consumption in advanced Western economies matter little to a bereft populace instructed to equate conspicuous consumption with the good life. Furthermore, the incidences of erratic weather triggered by climate change signify a more terrifying narrative of nature that had been bound and domesticated by the now-compromised ideology of science as progress. The state, that former paragon of Keynesian virtue,

has been revealed to the populace by the terrifying forces of financialization and nature combined as corrupt and ineffectual. Fear, anxiety, and a sense of dislocation permeate the popular consciousness.

The populace has declining value, or at least its value has declined within financial calculi. Its productive and consumptive capabilities have been rendered unsustainable by the crisis of a rentier capitalism that produced value through complex, abstract securitization processes. The populace now senses its declining relevance within the financial regime of governance that dominated the nation for the last 30 years. Yet, efforts to articulate this inchoate sensation are confounded by the technical vocabularies of financialization and the inability to enunciate the dynamics of the macro-level processes impacting individual lives. Accordingly, Kevin Rudd (2009) comments on the significance of the financial crisis in relation to its impact on the populace:

From time to time in human history there occur events of a truly seismic significance, events that mark a turning point between one epoch and the next, when one orthodoxy is overthrown and another takes its place. The significance of these events is rarely apparent as they unfold: it becomes clear only in retrospect, when observed from the commanding heights of history. By such time it is often too late to act to shape the course of such events and their effects on the day-to-day working lives of men and women and the families they support.

Although Rudd contends that the significance of events such as those experienced by the populace over the last two years is rarely acknowledged directly, it is the contention of this chapter that the significance of these events is being pondered in the collective consciousness of the nation in the form of a new genre of disaster films.

However, although the popular cinematic imagination expresses the senses of dislocation and disenfranchisement experienced by the populace, it can also contribute to deliberate efforts by financial and political elites to obscure the causal dynamics responsible for the crisis. As encouraged by cinematic representations, the crisis is therefore experienced in relation to inexplicable forces and agencies. Efforts to impose intelligibility on largely opaque relationships and dynamics have the unfortunate tendency to amplify the agency of petty sovereigns and tyrants. This tendency can be found across films in the forms of the cannibals in *The Road*, the local petty tyrant in *The Book of Eli*, and the soul-sucking carnivorous machine in *9*. This cinematic focus on petty sovereigns parallels the “real-world” vilification of financial authorities and Wall Street titans. While petty sovereigns do bear responsibility for harms, their scope of agency has been enabled by the matrix of systemic dynamics and relationships that produced the conditions of responsibility for the crisis.

Personification of agents of collapse in the form of petty sovereigns can result in a mystifying nostalgia. The time before collapse is cleansed, its inequities purged in the collective imagination. Post-collapse survivors therefore demand a return to a world that never existed. In particular, in the wake of the financial disaster, there has

been a resurgence of demands for a return to a form of laissez-faire, competitive capitalism that never existed as envisioned. Slavoj Žižek (2009) described a similar dynamic at work in the former Soviet republics, the populations of which began to engage in vehement, anticommunist rhetorics and policies. Žižek argued that the populations of these nations, many of which were themselves subjected to harsh austerity measures, erroneously blame communism for capitalism's failure to deliver its much-praised lifestyles to the majority of the populace. "In other words," he asserted, "the newly born anti-Communists don't get that what they are denouncing as perverted pseudo-capitalism simply is capitalism." In a similar pattern, the sophisticated zero hedge blog fans (zerohedge.com) and populist, low-brow Tea Party movement fail to recognize that what they perceive as the bastardization of free-market capitalism *really is* how capitalism operates when freed from strict regulatory oversight and constraints.

Capitalism, as regime of production based on the inequitable exploitation of value, created this crisis. Capitalism set the conditions of possibility for the rise of predatory, petty sovereigns and institutions. Capitalism produced the conditions of possibility for the dispossession of the population. And capitalism, that system that produced a biopolitics aimed at enhancing the productive capability of the population in order to extract surplus value, has also enabled clever entities and agents to devise strategies for acquiring wealth outside the traditional circuits of capitalist production through the expansion of rentier financialization. Post-apocalyptic disaster films like *The Road*, *The Book of Eli*, and *9* register the profound sense of dislocation experienced by the populace as they confront their superfluousness within a new social order cannibalized by finance capitalism.

NOTES

- 1 Thus, *Doomsday*, which is set in the United Kingdom, will be excluded from this analysis.
- 2 Bryan, Martin, and Rafferty (2009) do contend that financialization can still be analyzed within Marx's analysis of capitalist development in relation to the commodification of risk (p. 459).
- 3 Peck (2010) reports pessimistically in the *Atlantic* that:

The unemployment rate hit 10 percent in October [2010], and there are good reasons to believe that by 2011, 2012, even 2014, it will have declined only a little. Late last year, the average duration of unemployment surpassed six months, the first time that has happened since 1948, when the Bureau of Labor Statistics began tracking that number. As of this writing, for every open job in the U.S., six people are actively looking for work [. . .] The broadest measure of unemployment and underemployment [. . .] reached 17.4 percent in October, which appears to be the highest figure since the 1930s. And for large swaths of society – young adults, men, minorities – that figure was much higher (among teenagers, for instance, even the narrowest measure of unemployment stood at roughly 27 percent). One recent survey showed that 44 percent of families had experienced a job loss, a reduction in hours, or a pay cut in the past year.

A report on labor utilization by the Center for Labor Market Studies at Northeastern University (Sum, Khatiwada, & Palma, 2010) describes the contraction of the labor market:

The number of employed civilians (16+) in December 2009 was more than 9 million below its estimated level in November 2007, the month before the recession got underway [. . .] At the same time, the number of *underemployed*, i.e., those persons working part time for economic reasons, has also more than doubled, reaching a new record high of 6.4% of all of the employed in the fourth quarter of 2009. In addition, the nation's civilian labor force has actually shrunk by nearly one million over the past year rather than rising by 1.5 million as earlier projected by the U.S. Bureau of Labor Statistics. (p. 2)

This report argues that blue-collar and young workers are disproportionately impacted by unemployment and underemployment. Elizabeth Warren (2008) argues that nearly the entire US middle class has been imperiled by the financial crisis, a sentiment supported by Pew Research Survey results released in March of 2010:

Americans have little to cheer about. Nearly everyone (92%) gives the national economy a negative rating. Closer to home, 85% say that jobs are hard to find in their community. A majority (54%) now says that someone in their household has been without a job or looking for work in the past year, compared with 39% in February 2009. And the proportion saying they got a pay raise or a better job in the past year fell from 41% in January 2008 to 24% currently. (Pew Research Center, 2010)

- 4 This fear of fiscal deficits was exacerbated by the crisis in Greece. Greece ceded its monetary sovereignty in order to join the European Union. Hence, after speculators attacked Greek bonds by shorting them, Greece was forced to raise interest rates on its bond sales, thereby precipitating a sovereign debt crisis in the rollover costs of existing, maturing bonds.

Greening Cultural Labor

The Future of Media Accounting

Richard Maxwell and Toby Miller

ABSTRACT

In the early twenty-first century, environmentally friendly accounting practices in the creative industries were confined to site-specific budgets of individual films or studio operations. Any external environmental costs were either ignored or written off as too hard to measure. This chapter considers the media's future by imagining a new kind of accountancy freed from the bonds of corporate media. Richard Maxwell and Toby Miller have devised an imaginary world where accountants, imbued with the values of green citizenship, set off on a quest to uncover the environmental and labor conditions within the global supply chain of consumer electronics and information and communication technologies. This speculative fiction helps the authors conjure up conditions in which media producers and media studies scholars address human-centric despoliation of the Earth's ecosystems and the toxic exploitation of media workers.

Subject:	Tracking Carbon Emissions – Accounting Requirements

As part of News Corp’s Global Energy Initiative, all Fox productions must track and report on their carbon emissions. Accounting will be tracking carbon emissions throughout production and requires the following information from your department when submitting any documents for payment or reimbursement.

(Twentieth Century Fox, Guide to Greening Film and Television Production)

Introduction

Media studies has elevated many heroic figures in its self-fashioning mythology. Directors sidestep the studio system. Independents outwit the suits. Unions stand against management. Peripheral nations attract Bollywood and Hollywood productions. Journalists damn proprietors. Audiences outwit filmmakers. Film students stupefy professors. Downloaders defy corporations. Technologists astonish governments. Bloggers outpace professionals. Hagiographic stories inform the field’s prevailing myths of counter-power with narrative trajectories that have become banal and repetitive. In keeping with the desire for the new, we have sought a distinctly unglamorous and unlikely agent of historical change to add to this predictable pantheon: the accountant.

Why the accountant?¹ We are interested in a media future where ecologically sound principles guide cultural labor and media production. As it happens, accountants who currently work in large media organizations sit at the hub of information about the environmental costs of media production. This position gives the accountant, even one with no inherent yearning to be green, a vast and growing responsibility for measuring and reporting cultural work’s impact on the environment. Such green accountancy marks a salutary turn to environmentally friendly practices in the creative industries. But the confinement of this new form of accounting to site-specific budgets of individual films or studio operations limits its ability to assess the external environmental costs of making media, thereby also limiting the public’s awareness of the deleterious effects of what they consume and valorize.

In order for the industry to move beyond these confines, a new kind of accountancy must be imagined. In the middle section of this chapter, we offer a fictionalized version of accountants of the future who draw on environmental and union activism, scholarship, and public policy to free themselves from the bonds of the movie studio or site-specific shoot. A new kind of accountancy emerges at the cutting edge of media theory and practice in this forward-looking scenario. The new accountants’ odyssey leads to illuminating and frustrating encounters with the international political economy, which transform their perception of

cultural labor and measurement. As they envision a path to greener cultural labor, these future accountants are challenged by ecological questions that cannot necessarily be answered by measurement alone. We conclude with a return to the present-day view of the media's future.

2010: Blessed are the Accountants . . .

By late 2010, the professional and personal greening of cultural labor was already occurring in serious ways across the US, Japanese, and European culture industries. Cultural workers were being urged to follow environmentally sound practices on the job and, in the overreaching Fordist tradition of governmentality, during their non-work time as well. Major movie studios had programs that included installing low-energy light-emitting diodes to illuminate buildings, sound-stages, and outdoor signage; reducing paper use; composting organic waste; retrofitting buildings with computer-controlled air and heating systems and environmentally friendly materials; paying for reforestation with production budgets to account for film pollution; teleconferencing; recycling wood, paper, recording media, metals, film stock, electronics, and printer and toner cartridges; managing chemical use and disposal; reducing or eliminating hazardous materials; eliminating and recycling waste water; installing solar and other renewable energy sources; and networking with green suppliers and organizations such as the Greencode Project (Gardner, 2007; Producers Guild of America, n.d.).

These developments were encouraging to those wishing for a green media future, even though the culture industries came late to the realization that a slash-and-burn attitude to the environment was unsustainable. Their eco-ethical awakening can be dated from the period between the mid-1990s and 2010, somewhere between *Titanic* (1997) and *Avatar* (2009). The primitive state of this transition to greener production is evident in the accounting offices of the large studios – the point on the organizational chart where green means business. Consider our opening epigraph to this chapter, a heading from the sample memo to production workers found in Fox's *Guide to Greening Film and Television Production* (n.d.). As in most large organizations, the accounting office operates as an informational nodal point between management and labor, particularly where the audit of material expenditures details inputs of capital and energy into production. It is a matter of expediency to make accountants working in media firms responsible for tracking carbon emissions via purchases entered into debit columns on spreadsheets. A small set of transactions has come to denote carbon emitted from filmmaking and TV production: gallons of fuel, nights at hotels, board feet of lumber, air miles traveled, kilowatt hours burned, and so on.

In the early twenty-first century, studio accountants are expected to know how much carbon the movies emit: small films are said to generate 145 tons; middling shoots, 970 tons; fast and furious, 4,000 tons; and so on ("Calculating," 2010). The political economy presses hard to keep this green knowledge in the service of business

as usual (BAU), which means that if dirty air can be quantified, it should be monetized, with ethics just another word for nothing left to regulate. Enter the market for carbon offsets (indexed to a firm's reduction of carbon dioxide and other greenhouse gas emissions), where organizations seek investment for green innovation or buy credits to plant trees or fund someone else's green company. Carbon offsets serve as the primary currency paid by or to a media firm to cover environmental behavior.

This arrangement limits the scope of environmentally sound production practices in the creative industries, because whatever cannot be counted cannot be included in the accountant's impact assessment: for example, material or labor costs outside the production sites overseen by accounting, on supply chains that are upstream or downstream of creative productions. Accountants know the price of electricity and phone calls, but cannot include an audit of carbon emissions generated by their suppliers in the energy and telecommunications sectors; they know how much hazardous waste a film or TV shoot produced, but have no way to tally and monetize off-site environmental emissions from recycling, incineration, long-haul transport, or the costs associated with dumping toxic waste into landfills. Cultural labor beyond local production is not among the green accountant's line items. It did not help matters that existing environmental accountancy focused entirely on natural resources as an asset in general economic welfare accounts.² In order to implement an accounting system that was adequate to the global scale of green media accountancy, a new kind of accountant was needed. The following section describes an approximate world where we find the accountant of the future.

Sometime in the Near Future³

The situation in 2010 necessitated a new kind of accountant, one who would take the virtue of accountancy's *modus operandi* – count everything! – and dedicate it to finding out how cultural labor and the environment connected beyond the gates of the studio. Such an endeavor would have to identify international flows of toxic materials, intersectorial and transborder carbon emissions, and other environmental harms that accompany cultural labor worldwide. This holistic and global purview was underdeveloped in governmental and academic studies. As the new accountant would come to realize, this was not a failing of desire or will on the part of these researchers. Right-wing, nationalistic politics, along with global business lobbies, hindered the already herculean task of gathering accurate data on an international scale. It was virtually impossible to track the sources, volume, and destination of even discarded media technologies, the electronic waste (e-waste) of dead or obsolete computers, printers, peripherals, music players, cell phones, ink cartridges, and other tools of contemporary media production. One typical study from 2010 concluded that even “*estimating waste flows is not an easy task [. . . and] has to be determined on the basis of often scarce information*” (Zoeteman, Krikke, & Venselaar, 2010, p. 416, emphasis added). Another investigation from the same period argued that

existing “accountancy rules, purchasing policies and reporting standards do not consistently require attention to environmental externalities – including social costs due to impacts on ecosystems and biodiversity” (TEEB, 2010, p. 27).

Accountants of the future faced many challenges. One of the most daunting was scale. Tens of millions of workers built the world’s information and communication technology (ICT) sector alone, with numbers continuing to grow in accordance with the New International Division of Cultural Labor (NICL), which has seen cultural production go offshore from cultural ownership, in the same form as automobile or computer manufacture (Miller, Govil, McMurria, Maxwell, & Wang, 2005). The new accountancy learned to comprehend this scale of labor⁴ only to be infuriated by media owners’ opposition to ever fuller disclosure. Media owners justified their opposition with a mixture of legal arguments about proprietary information, business freedom, and respect for national sovereignty (the Chinese were most adamant, deploying the sovereignty argument to protect illegal e-waste businesses in the ecological dead zones of the Pearl and Yangtze river deltas). Such powerful resistance incited the accountants’ demand for an end to the existing system, which obscured the number of workers in the global supply chain and undermined accurate assessments of the jobs that produced waste byproducts, harmful substances, and other measurable environmental inputs. This became the start of a long revolution for the new accountancy, with most successes based on a clear and persistent alliance with labor unions, environmental activists, and researchers who had struggled in prior decades to generate accurate statistics on workers and working conditions in the global media, ICT, and consumer electronics (CE) sectors.

The new accountancy became increasingly militant in its struggle to count everything and everybody in the international division of labor. This radicalization was based, somewhat ironically, in a collective realization that the quantification of populations had emerged from contradictions in the capitalist political economy that linked surveillance, social control, and liberation. This nexus would not only enable corporations to exercise absolute authority over a workforce, which was technically free in that its members could resign if they so wished. From the perspective of the radical accountant, it also provided conditions for information to be used against the powerful. The division of labor that the accountants of the future fought to evaluate had not evolved into the transparent system that classical economics long ago predicted – in terms that the pioneering social scientist Emile Durkheim (1984) chided for promising a “higher law of human societies and the condition for progress” (p. 1). Rather, as the Marxists had shown, capitalism shaped the division of labor into a key mechanism of power and control by subdividing work, multiplying its inputs, and spreading it unevenly across the planet. The interconnectedness of workers that constituted the progressive dimension in the division of labor – Workers of the World Unite! Solidarity Forever! – was obscured to those working within it, while being perverted and exploited by those with command over it (Marx, 1906, pp. 49, 83). The accountant of the future vowed to fight for as long as it took to achieve numerical transparency, not for the bosses but to reestablish the ties of workers (if only statistically at first) up and down the interlocking supply chains of media and ICT/CE production.

The first positive result came with the start of a systematic correction of spreadsheets in the global human resources system, which had hitherto depicted occupational extremes between a total system of surveillance of workers and those “disappeared” from the rosters. For instance, the new accountancy expanded its purview to include data on the number of people extracting the metals that went into electronic media devices. The new data went beyond the 4,000 people known to accountants in 2010 to include biographies of a growing portion of the 13 million people said to work in the informal mining sector in Asia, Latin America, and Africa (GeSI & EICC, 2008, p. 56; International Labor Organization, 2010). With the help of labor unions, nongovernmental organizations, local activists, policy-oriented journalists, and even some corporate social responsibility audits and social networking sites, the new accountancy revised the count of ICT and media workers to over 200 million worldwide, from earlier estimates of 70 million (Raina, 2007, pp. 18–25).

Despite constant interference and threats from corporate lawyers, the American Civil Liberties Union, and non-independent (company) trade unions, a statistical picture emerged that revealed organizational relationships, intersectorial linkages, and regional points of alliance unacknowledged by the old accountancy. Eventually, the new accountants identified assemblages of interconnected labor in global media production and measured the impact of the chemico-mechanical processes attendant to each line of work: including, among others, computer scientists, engineers, designers, market researchers, miners, mineral brokers, refiners, chemists, factory laborers, server-warehouse employees, telecommunications workers, truck drivers, salespeople, office clerks, and above- and below-the-line media production workers. Not only could the new accountants identify and count vast numbers of workers throughout the supply chain; their technique also provided ways of tracking emerging constituencies of workers, from elemental stages of mineral extraction to home assembly.

They achieved much of this new and improved, more labor-inclusive, accounting program by internationalizing data collection and installing an ethnographic dimension as part of their research methodology. The new accountancy benefited from learning world languages and cultivating a professional delight in cultural differences – they identified many new facets of everyday life affected by the global supply chain. Some older practitioners saw these worldly and polymathic characteristics as a welcome recovery of a twentieth-century notion of the humanities – one that informed interdisciplinary and internationalist ideals lost by public higher education by the end of that century. For the accountants of the future, in contrast, nostalgia and highfalutin principles had nothing to do with acquiring these capabilities; these were fundamental skills needed for the job ahead.

The data were informative; the *personal* aspects became transformative. As numbers gave way to faces, life stories, and human struggles, the accountants of the future imagined unorthodox ways to combine ecological perspectives with biographies in global assembly lines. They tried to quantify these connections, struggling to find the right algorithm for measuring the environmental cost of geographical co-presence in the NICL. They could budget for the gaffer in Hollywood eating sandwiches on

biodegradable bamboo plates while on breaks from handling cables, monitors, and advanced electronics. And they could perceive how that gaffer related to teenage girls in Mexico who assembled those technologies in conditions that denied them lunch-time luxuries and exposed them to toxic materials.⁵ But they could not enter these relationships into the calculus.

These challenges did not stop the new accountancy from developing methods of calculation unknown to the old system of green audits. To the accountant of the future, earlier so-called green auditing procedures appeared ludicrously narcissistic in hindsight, because they focused on media producers' own growth-based criteria for evaluating the economic performance of the "creative industries" (a term from the early twenty-first century that summed up the narrowness of their world view). The old-school criteria had valued such environmentally harmful economic activity as building new, electricity-guzzling server warehouses equally or more than green innovations.

Scientific knowledge posed a second major challenge for the new accountancy, which experienced a steep learning curve in trying to link cultural labor's environmental impact on the scale of the NICL. The accountants of the future learned of biothermal risks to workers and consumers exposed to human-made electromagnetic fields, and scientific parameters for human tolerance to these forces. They learned the basic toxicological properties of carcinogenic and poisonous gases, metals, and chemicals used in ICT/CE manufacturing, unpacking a daunting array of elements, synthetic compounds, and their effects on human health: aluminum, antimony, barium, beryllium, cesium, chromium, cobalt, copper, gold, lead, mercury, molybdenum, nickel, platinum, silver, tin, titanium, tungsten, zinc; acidic cupric chloride, alkaline ammoniacal, sulfuric peroxide, argon, arsine, silane, phosphine, arsenic, selenium, polychlorinated biphenyls, trichloroethylene, ammonia, methanol, glycol ethers, methylene chloride, nonylphenols; and so on.⁶ For all along the international division of cultural labor, workers were exposed to combinations of these materials, with serious consequences to their health.

Some chemicals had short-term effects, such as skin and eye irritation, headaches, vertigo, and nausea. Others had to be absorbed into the blood stream over longer periods before harmful disorders could be diagnosed. Then there were the bioaccumulative toxins that would collect in fatty tissue; these were long understood to flow up the food chain through land and waterways before being consumed by humans and taking up residence in their bodies. There was another class called endocrine disruptors, found in many plastics, which upset normal functioning of the endocrine system by acting as if they were human hormones, leading to a variety of harms (cancers and other problems in reproductive systems, thyroid, metabolism, etc.). One of the most dramatic ways the new accountancy found to illustrate the longevity of these pathogens in the environment was to borrow from research on e-waste, which provided a testing ground for the effects of open exposure to the chemical and heavy metal content in ICT/CE (Leung, Duzgoren-Aydin, Cheung, & Wong, 2008; Ray, Mukherjee, Roychowdhury, & Lahiri, 2004; Wong, Wu, Duzgoren-Aydin, Aydin, & Wong, 2007).

Enclosed hard drives, backlit screens, (increasingly rare) cathode-ray tubes, wiring, capacitors, and metals like gold, silver, and lead posed few risks while these toxic materials remained encased. In contrast, discarded electronics had the potential to expose workers to a salad of toxic components when dismantled. Parts could be reused or swapped for newer parts to refurbish older devices. But those targeted for the waste stream underwent further destruction in order to collect remaining parts and metals of value (gold, silver, copper, and rare-earth elements are examples). That was when serious health-and-safety risks occurred, including bone disease, brain damage, birth defects, diseases of the stomach, lungs, and vital organs, and disrupted biological development in children. These conditions resulted from exposure to heavy metals (lead, cadmium, and mercury, among others), dioxins emitted by burning wires insulated with polyvinylchloride, flame retardants in circuit boards and plastic casings containing polychlorinated biphenyls, and poisonous fumes emitted in search of precious metals (Leung et al., 2008; Ray et al., 2004; Wong et al., 2007).

The accountants of the future determined various ways to calculate the environmental cost of toxins that outlasted the devices containing them. This was an important achievement, given that existing methods for measuring the impact of toxic e-waste primarily consisted of tracking the volume of sales and disposal of electronics and electric devices (Schor, 2010, pp. 32–37; Zoeteman et al., 2010, p. 418). The longevity of pathogens had to be quantified and entered into ledgers along with other risks associated with damages to ecosystems. The valuation was carried out using a model that assessed ecosystem services and biophysical benefits as economic inputs – for example, multiple relevant ecosystems added value to media and ICT/CE production, from the marine and desert biomes that endow the Southern Californian climate to the ecosystems providing food, water, and housing to cultural workers worldwide. The new accountancy added the costs incurred when waste, harmful byproducts, or other neglectful practices associated with media production devalued ecosystem services.

The method worked for a short-range projection of the costs of such damage, but was of little use in long-range valuations. The problem was setting a discount rate that compared present and future costs of environmental damage. Given the ethical dilemma of determining the value of ecosystem services for future generations, it was not practical to use existing economic models, which assumed that technological fixes would reduce the cost of ecosystem repair – for example, yet-to-be discovered nano- or biotechnology that could consume plastic or neutralize toxins. The new accountancy was uncomfortable with the idea that an accurate count of long-term costs was impossible, though practitioners agreed to present “sensitivity analysis of cost-benefit-ratios using a range of different discount rates [. . .] to highlight different ethical perspectives and their implications for future generations” (TEEB, 2010, p. 26). This compromise would become untenable as more time, and eventually more weight, was given to ethical understanding of the environment’s future. A turn to ecological ethics in the new accountancy was underway.

The limits to calculating intergenerational impact confounded the new accountants, who had striven to understand the geographical scale of the NICL and the

interconnectedness of cultural labor over time. They simply could not trust the very cost-benefit numbers they had produced about the future. Unlike climate scientists, who looked to the geological past to help predict changing atmospheric conditions, the accountants of the future could only offer probabilities based on political trends and BAU. This produced a list of general changes in the relationships of the environment to media and ICT/CE production: for example, in the absence of a massive rollout of public works worldwide to build clean energy systems, a greater proportion of greenhouse gases would probably come from media sources such as server warehouses, where electricity consumption was rising 150% a year on average, while residential ICT/CE equipment was projected to take 30% of global electricity output by 2022 and 45% by 2030 (International Energy Agency, 2009, p. 21; International Telecommunication Union, 2009, p. 4). Accountancy did not do well with such generalities. Even if these projections could direct action toward particular futures like energy-efficient production plants, smart grid/residential metering, or abundant low-wattage entertainments, there would also be unpredictable outcomes, from scientific discoveries to catastrophic events. Such uncertainty took the accountant far from the comfort of cost-benefit analysis (CBA), a beloved risk-management tool for monetizing human and nonhuman effects of environmental change. CBA could not account for intergenerational changes; and it did not work under conditions favoring interterritorial equity, which the new accountants sought to measure as they overcame ethnocentric assumptions about the relative value of cultural labor living across national borders or intranational lines of difference.

The accountants of the future had entered a domain where eco-ethical thinking proved a more powerful tool than CBA and other accountancy methods. They continued to count the numbers of US federal prisoners and pre-teen Chinese, Nigerian, and Indian girls picking apart electronics for precious metals or reusable parts.⁷ But that kind of quantification could not pinpoint the human and environmental cost of dust laden with toxic heavy metals from circuit boards and other components inhaled or blown afield from recycling sites, or the harm associated with exposure to multiple sources of electromagnetic radiation.

This shortcoming resulted from the physical difficulty of establishing and measuring the risks faced by all planetary inhabitants.⁸ It illustrated a limitation to the discourse of risk management, which focused on how particular pathogens were allocated across populations, rather than seeking to eliminate such risks altogether. From an eco-ethical standpoint that valued human and nonhuman nature alike, any effort to measure and manage “safe amounts” of exposure to toxins and pollutants was a dirty ideological game. The new accountancy saw this as a remnant of washed-out “modernity,” wherein everyday life could progress only under persistent threats to well-being. The new accountants refused to be a part of the propaganda of “risk society,” which naturalized these threats using future-oriented scenarios that were based on a self-aggrandizing cocktail of fragile numbers and faith-based predictions. They knew too well how such calculations of chance could freeze critical thinking and rouse thoughtless decisions that only served to metastasize harmful outcomes.

Ecological ethics, in contrast, offered a considerate and sensible alternative: assuming that humans were ignorant of the future effects of present-day action, adopting a deep regard for the natural world, and acting with caution rather than hubris when establishing a human presence within it. The new accountancy established guidelines that placed an extremely rigorous burden of proof on media and ICT/CE producers, who claimed that their business strategies would not introduce harmful substances or practices into the environment. In some cases, where there was scientific consensus about the chemical-mechanical processes used in the supply chain, the approval process was quite streamlined. Many progressive producers embraced the “better safe than sorry” environmental principle introduced by their green “bean counters.” Others resisted, among them a very vocal, obstinate group of climate change-denying media owners, most of whom were caught in the paradigm of business school accounting methods introduced in the 1970s. This group would soon be squeezed by an unlikely coalition of twenty-something and eighty-something media makers who joined the green cultural labor movement that had been growing within the global cultural industries.

This division between eco-ethically guided producers and BAU manifested itself in an ideological battle. The former promoted the virtues of sustainable media making. The latter promised abundant electronic and visual pleasures pulsating with innovative design and symbolic power. The BAU types had the upper hand in this war for hearts and minds, and enjoyed some success in fighting the spread of the new accountancy through union busting and monopoly practices that locked out green competition. But the sustainability coalition began to expand exponentially as green alliances formed across the political spectrum. Increasing numbers of media business owners and policymakers came to understand that the information, entertainment, and educational aspects of the media could prosper within a modest revenue model based on a mature and honest environmental accounting system that prohibited all practices that are not indefinitely sustainable by the Earth’s ecosystems. The BAU faction continued to reap huge profits from selling ever more ingenious gadgets that were built within its network of suppliers, in regions unregulated by green guidelines, and sold in markets where policymakers feared the revolt of voters who saw any prohibition on their consumption of high-tech goods as a threat to freedom and choice.

The accountants of the future realized their goals to increase the accuracy of measuring environmental costs, broaden the categories of labor involved in media and ICT/CE production, and forge a new calculus that clearly delineated how to make cultural labor greener throughout the global supply chain. The limits to accountancy’s role were in part transcended by the turn to eco-ethical deliberation. Once the new accountancy crossed the threshold toward legitimacy on a multinational scale, there was a dramatic and immediate effect on the outlook of global business, as the addition of environmental accounting to the bottom line created an epidemic of “writedowns,” which caused green businesses to operate in the red for over a decade.

At first, this gave a boost to the BAU faction, which enjoyed a rush of investment from financial markets (historically intolerant of environmentalism, in any case). This appeared to weaken the green faction, which BAU briefly succeeded in defeating on political and economic fronts. Eventually, however, three major institutional changes propelled green practices into the forefront of a new, vibrant media economy. First, policymakers in key regions – China, India, the European Union (EU), Brazil, Canada, and Japan – established social funds from which green media organizations could draw in order to invest in long-term, sustainable practices. This countered other market pressures, which favored BAU. Second, larger conglomerates closed their worst polluting properties or invested in resource replacement, turning formerly wasteful, toxic practices into efficient, clean operations (simple changes in chemistry and fiber resourcing, for example, made paper production viable again). The debt incurred by firms was high at first, but the pay-off came via lower environmental costs. Small- to medium-sized media/ICT/CE production companies bought polluting properties and transformed them through available technologies funded by environmentally oriented venture capitalists. The thinking here was that the green accountancy was right (on the money) for medium- to long-term revenue generation, and that only a fool would believe that ignoring environmental costs in bookkeeping could provide lasting advantages in the marketplace.

Finally, the asymmetrical takeup of green products in the largest consumer markets – the EU, the United States, India, China, and Brazil – began to shift as marketers realized that the European practice of consumer education in green product quality did not diminish sales. US regulations had not changed effectively for 20 years, allowing a continuous flow of toxic-laced products to be sold there; whereas in the EU, regulators had ensured that media products and consumption were indexed to ecological enhancements, which improved the quality and lifetime of technological goods, reduced the consuming frenzy for ephemeral fashion/style in consumer goods, and underwrote the policy of extended producer responsibility for electronic and electric goods. Consumers loved the result: they bought high-quality media technology built on green service principles. When real (i.e., noncosmetic) innovation made the gadgets obsolete, the brand-owner would upgrade or replace the device at a price that would either be tied to the minimal changes in the new components or was already paid for in the original purchase. (Most top brands in Europe had eliminated virtually all waste and discovered designs that allowed for nearly complete reuse of the component parts.) It took some time for production practices throughout the supply chain to reach ecologically sustainable benchmarks, but eventually even the brands designed as well as made in China and India, once egregious polluters though early innovators in state-based green technology, surpassed the neoliberal United States in green media production.

Green accountancy had established a new paradigm for cultural labor. Institutional changes generated a steady stream of information about successful green cultural labor and technologies, with fact-filled reports shared widely in business and government circles. But this hegemony remained vulnerable to challenges from BAU, which

persisted in its ambition to end the “reign of tree huggers.” This highly capitalized faction of media owners could not tolerate the growing consensus on sustainability lest it ruin their empires.

As in the past, BAU relied on parallel lines of attack – mass persuasion and control over the political processes – focused primarily in the United States, where it was easiest to control political discourse and where domination of a huge consumer market helped fund political ambitions. Through media and communication channels, propaganda convinced consumers that green media technology was a scam. The bourgeois media depicted suffering and hard-working consumers locked out of the good life by expensive green technologies while portraying themselves as providing affordable electronic and electric pleasure to the downtrodden. “The green companies must think you are chumps,” was one typical retort from a BAU-sponsored commentator. Such rhetoric, which played on the economic self-interest of consumers, was a powerful distraction from the evidence of sustainable, successful eco-ethical practices.

The BAU faction also spent large portions of its wealth on political candidates whose campaigns spread fear of big government, foreigners, and socialist plots aiming to smash freedom of choice and economic growth. This strategy won many battles. But in the end, their share of the market diminished as consumers, investors, and policymakers realized that their accounting system fostered too many costly gaps, not least the accurate measurement of environmental impact. With losses came increased resentment within the remnants of BAU, which retreated from politics for a time in order to regroup, form new alliances, and build a movement to win back their access to hugely profitable business. That’s another story.

Conclusion

The preceding speculative fiction imagines some conditions of possibility for green cultural labor to prosper in a world whose political-economic arrangements favor movements to counter the twentieth century’s despoliation of the Earth’s ecosystems. Our choice of an “accountant of the future” as an environmental hero is somewhat whimsical, though it was inspired by present practices within media firms that position accountants as pivotal agents of change in greening cultural labor.

The hopeful scenarios in our imagined media future are conveniently disengaged from the present political economy, which is hardening into a new Gilded Age, where wealth concentration and hyperconsumption, even in depressed economies, freeze critical thinking about climate change and the means to achieve policy and public/private investment for ecologically sound economies – public transportation works, alternative energy, low-wattage entertainment, green technologies, and so on.

In today’s United States, right-wing demagogues rail against foreign influences and climate science, two sources that provide scores of real-life examples of how

large- and small-scale human practices are reducing greenhouse gas emissions and toxic waste. Green design initiatives surround us as we write, but the built environment and consumer goods continue to be defined by a passion for fossil fuels and non-biodegradable plastic (Schor, 2010).

Our call for better media accounting was provoked by the fact that corporations and governments in the Global North are currently sending toxic e-waste to other countries in the absence of a clear measurement of the volume of trade in these poisons. In addition, the global supply chain depicted at the outset of our story is not unlike the one we find today – workers uncoun- ted and unknown, living, ailing, and dying across a vast assembly line in which present-day wonders are manufactured. Our fictitious militant accountants were frustrated by lacunae in existing policy regimes, which, while laudable in many ways, fail in most attempts to find the political resources for effective accounting and policy implementation. Japan, Canada, and the United States still undermine the 1995 Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal, which prohibits the transport of dangerous material (United States Government Accountability Office, 2008, pp. 23–27, 24 n. 22; van Erp & Huisman, 2010). And yet, we have seen hopeful signs in legal investigations of unlawful e-waste exports to West Africa (Walsh, 2010), the recodification of e-waste business as global organized crime (Criminal Intelligence Service Canada, 2008), and EU efforts to license and oversee e-waste exporters, traders, dealers, and brokers (van Erp & Huisman, 2010).

We have based the ethico-political values of our media future on “green citizenship,” which presses for basic rights that include clean air and water, for the acceptance of interterritorial and intergenerational responsibility to care for the Earth’s ecosystems, and for business corporations to pay for the social and environmental resources they exploit. We have tried to imagine the contradictory and complicated endeavor required to bring such rights into existence with a view to the future, which in our fictionalized version ends up almost confounding the new accountancy. As we have argued elsewhere, this kind of intergenerational thinking must pervade media studies if we are to confront our logocentric interdependence on the technology we engage with, criticize, and promote (Maxwell & Miller, 2008d).

The battle of future accountants against the purveyors of BAU media is also a battle against the current enchantment of technology and technological fads, which have worsened the ecological crisis. The connection between gadgetry abundance and planetary decline is only beginning to enter the critical curriculum of media studies, though environmental activists have been examining this relationship since the 1980s. The need for a new kind of accountancy was clear then, as activists and other researchers struggled to break the informational barrier erected by media and ICT/CE businesses. Like our imaginary accountant, media studies of the future must enact an Earth-centered ecological ethics to keep in check the managerial, human-centered tendencies of CBA that fracture a holistic understanding of the relationship of media technology to the environment. Along these lines, media studies could moderate the temptation toward preemptive conclusions by using the

precautionary principle that enabled accountants of the future to transcend conventional quantification.

At present, the limits to understanding the extent of the environmental impact of technology and cultural labor in the Global North, and hence the means to green these, are said to result from three reporting failures:

- 1 Cultural workers and consumers throw waste and byproducts into the traditional waste stream, where the items cannot be counted and are eventually lost in landfills and incinerators.
- 2 Nefarious forces hide the volume of illegally procured and traded e-waste in order to continue profiting, either through global salvage or the more benign-sounding business-to-business trade.
- 3 Government-run systems of waste control poorly educate and inform workers and consumers about depositing e-waste where it can be counted, while failing to enforce laws meant to coerce waste-producing industries to declare all items.

All three explanations are correct. They necessitate changes in the current system to place green citizenship and green governance at the center of the action. Perhaps the radically reconfigured notion of environmental accountancy and auditing we have envisioned here can provide a way for media studies to imagine its own transformative role in a future of environmentally sustainable media industries.

NOTES

- 1 The thrilling nature of accountancy has been established ethnographically, lexicographically, and rhetorically (Flowerdew & Wan, 2006), not least in Monty Python's vocational-guidance "Lion Tamer" sketch ("dull, dull, dull") with its "League for Fighting Chartered Accountancy." You don't marry such people for the ride of your life, even if they have a sense of humor like Sacramento, California accounting firm MGO, which adopted the slogan "Proud to Be Boring Accountants" in 2010 (<http://www.mgocpa.com/go/mgo/?jsessionid=EC11314641BFF963CA5F3F14BBCDE75F>).
- 2 See, for example, Jones (2010); Rahaman (2010); the websites for Critical Management (<http://www.criticalmanagement.org/>) and Critical Management Studies (<http://group.aomonline.org/cms>); the journals *Critical Perspectives on Accounting*; *Accounting, Organizations and Society*; *Accounting, Auditing and Accountability Journal*; and *International Journal of Critical Accounting*; and the currency of "technology foresight," which sought to address the problems caused by innovation (Miles, 2010). Scholarly work on environmental accounting began in the early 1990s and over the next two decades developed to include environmental danger, corporate responsibility, new relationships between industry and the environment, systems of measurement, and reporting norms that the United Nations' Division for Sustainable Development's expert working group on the topic produced, which included a comprehensive Environmental Management Accounting methodology (http://www.unep.ch/etb/areas/VRC_index.php). The US Environmental Protection

Agency (2007) offered a limited but useful guide. The International Accounting Standards Board began to pay heed (Gale, 2006; Jones, 2010), and firms appeared to provide such services (<http://www.greenaccountancy.com>). Environmental accounting is a far cry, of course, from many norms of the industry. One of us worked as a credit analyst for a major US overseas bank in the early 1980s. As part of welcoming visiting metropolitan dignitaries to the colonies, local operatives diligently crop-dusted a bar-b-cue area near a mine three days prior to their arrival to ensure they would not be inconvenienced by insect life. The environmental impact appears not to have made it into the accounts.

- 8 Of course, the new accountants were aware that it was possible to ascribe a value to the physical damage caused by exposure to toxic dust, but the cynical nature of the process sickened them. Case in point: in 2010, a US court determined that workers exposed to poisons in the ruins of the World Trade Center were worth at most about US\$81,000 apiece. The price was indexed to the loss of good health caused by the failure of government and business to provide protection to “first responders.”

Introduction

Media Studies Futures, Past and Present

Kelly Gates

ABSTRACT

Of necessity, the field of media studies no longer focuses exclusively on the conventional categories of television, film, radio, and print. Distributed digital networks, new types of hardware and software configurations, and new institutional arrangements in the media industries are disrupting existing categories and challenging theoretical and methodological approaches. How can media studies best make sense of changing media institutions, forms, and uses? How will the field keep pace with changes in media occurring in the decades to come? What will the “new media” of the future look like, and how can media studies help shape that future? *Media Studies Futures* highlights some of the major challenges and opportunities facing scholars, students, and advocates interested in understanding our changing media forms and working toward realizing their democratic possibilities. The main themes addressed here include: (1) media theory, methods, and pedagogy; (2) social and mobile media; (3) media industries and infrastructures; (4) journalism and media policy; (5) interactivity, affect, and media subjectivities; (6) children and youth cultures’ uses of digital media; and (7) media waste and sustainability. The aim of this work is to promote a more open and inclusive discussion of the future possibilities for media and media studies, challenging rather than participating in dominant tendencies to lay claim to any particular future of media or their field of study.

Media Studies Futures, Past and Present

Having a group of scholars comment on key topics and issues for the future of media studies in a printed and bound book seems paradoxical today, given the slow pace of book publishing and the seeming inadequacies of the print form to capture the world of networked media environments. The book form itself, once known primarily as a bound collection of printed pages, is being refashioned for digital networks, in complex relationship with changes occurring in modes of publishing and distribution as well as authoring, writing, and reading practices. Even before the Kindle, the Nook, and the iPad, digital technologies were transforming the book from the inside out, as writers adopted word processors, and as printers moved to screen-based forms of movable type. Google's massive project of book remediation, while in some ways breathing new life into old bound books, has also pushed the world of books that much further toward a total transition from print to screen. Now, even old printed books can be refashioned in networked form, complete with embedded hyperlinks. The bound paper analog form of the book seems an archaic place to be discussing the future of media.

Before moving too far along the path of an apology for the form this collection of printed essays takes, I want to instead qualify the volume's title. The aim of compiling a collection of work under the heading of *Media Studies Futures* is not to make a definitive statement about the directions the field is taking. Rather, the goal of this volume is to bring together works that collectively challenge any monolithic statement about the future of media and media studies. The principle unifying point that emerges from the diverse body of thought gathered here is that media studies needs to take seriously the fact that *radical uncertainty and contingency* are the only features that define where media and media studies are headed.

There are both risks and rewards in defining the future of the field and its objects of analysis in this indeterminate way. Without a doubt, people who make it their business to study media need to engage in debates about the future. We should put forth visions of that future that embody the values we hold dear, investing the field with the strongest possible chance of renewed relevancy. But lest we merely adopt the language of actors with very different stakes in what the future of media will look like, we should examine the direction of the field with a reflexive sensibility. In other words, media studies practitioners need to engage in this debate fully cognizant that there is not one future of media or media studies, but many possible futures, and those futures are *impossible to know or determine in advance*. In the wise words of the late James Carey and his colleague John Quirk, the future "never quite makes its entrance into history" – it is by definition a time that is always awaited but never arrives (Carey & Quirk, 1973, p. 485).

Taking a cue from Carey and Quirk, we can find valuable lessons about the future and its uncertainties by looking to the past, or, more specifically, to *the history of the future*. In his historical analysis of how people perceived the future in the "culture of

space and time” (in the West during the period 1880–1918), Steven Kern (1983/2003) emphasizes the wisdom of French physicists and philosophers of the time, like Emile Meyerson, Henri Bergson, and Jean-Marie Guyau, each of whom in their own way insisted that an uncertain, open future was essential to the very possibility of human freedom. In their view, a predictable and certain future did not portend well for the idea of free will or the possibility that people might be able to actively change their circumstances.

In 1931, the *New York Times* asked a selection of prominent figures of the day about their projections for the future “eighty years hence.” In his contribution, Henry Ford made the interesting and tentative suggestion that “perhaps our most progressive step will be the discovery that we have not made so much progress as the clatter of the times would suggest.” Ford insisted that “the only profit of life is life itself,” and hoped optimistically that “the coming eighty years will see us more successful in passing around the real profit of life.” It is of course 80 years later, and it is difficult to conclude in these tough times that the real profit of life has been passed around. For every example in that regard, there are many counterexamples. But there is at least one qualified example worthy of note that might support Ford’s hopeful vision, even if it was not precisely what he had in mind. When the *New York Times* published this feature, it included only the views of elite white men. Predictably, if not very prophetically, none of the writers had a single word to say about the changes that might occur in gender relations, or the advances in status that middle-class women would make. Perhaps the “modern woman” was able to make such progress during this period precisely because few bothered to foretell how far she would go.

Of course, contemplating the future presents endless paradoxes. One of the reasons why people are so interested in trying to predict the future is to give themselves a feeling of control over their fate (Ropeik, 2010). Presently, the inventor Ray Kurzweil perhaps best embodies the figure of the futurologist, driven by an intense desire to predict and control the future. He famously forecasts that the world is headed toward “the singularity,” an event horizon when humans will completely merge with computers, giving birth to a new superhuman race of hyper-intelligent cyborgs. Although some dismiss Kurzweil as an Internet-age quack, others are more receptive, including the likes of Bill Gates, Sergey Brin, and Larry Page (Vance, 2010). A documentary about Kurzweil, called *Transcendent Man* (Robert Ptolemy, 2009), portrays him as a person profoundly motivated by a desire to control his fate and especially to beat death. The film also depicts him as the quintessential technological utopian. For David Golumbia (2009), author of *The Cultural Logic of Computation* and a contributor to this volume, Kurzweil’s ideas are profoundly shaped by a “computationalist ideology.” For Kurzweil, everything is already computation, so it only makes sense that the future is computable as well. Even better, every worldly problem will eventually be solvable with more processing power and well-designed computer programs.

Computers and computation are deeply implicated in future-prediction, so much so that we cannot talk about the future without taking them into consideration. Nor

can we fully understand the relationship between computerization and social change without considering the ways computation is used to actively envision and intervene on the future – from the computer-generated imagery used to portray the future in science fiction films, to the computational algorithms used to predict the behavior of the financial markets. Simulation technologies in particular are designed precisely for this purpose, using computational analysis to render virtual representations of ostensible future realities. Simulations have become so commonplace that Baudrillard's once-provocative statement – that simulation has rendered reality obsolete – seems almost quaint today, the basis of countless movie plotlines (Baudrillard, 1983). Hollywood has produced enough copies of *The Matrix* (Wachowski and Wachowski, 1999) by now that the simulation trope itself has become a precession of simulacra. Seeing yet another simulation story cannot help but make us nostalgic for a time when the idea seemed original. In fact, as William Bogard (1996) has argued, the logic of simulation is deeply imbued with a sense of sentimental recollection, positing the future as essentially a course of events that has already happened. For all of the hype surrounding its future-predicting potential, notes Bogard, simulation technology is “more about a kind of nostalgia or melancholy for the future; it produces a sense that the future is not ahead but in some fundamental way already over” (p. 23).

Whether they invoke nostalgia, great expectation, or resignation, many of the stories about the future that late capitalist societies tell themselves are formulated via computation, and manifested in digital media of some form. And while the veracity of the output is uncertain, it cannot help but have an influence on both *ideas* about the future and important future-shaping decisions being made in the present.

But even before computerization, the future and its prediction was a familiar story. According to the philosopher Langdon Winner (1996), the basic tendency of modernism to convey the future as already decided could be found throughout the twentieth century, as the terms of the social contract were defined according to the priorities of capitalist economic development. In the prevailing version of the future on offer, “people were to be propelled forward by forces larger than themselves into a world that was rational, dynamic, prosperous, and harmonious” (Winner, 1996, p. 67). At the 1939 New York World's Fair, for example, the future was presented to visitors as a spectacular experience – a perfectly functioning technological environment portrayed as a foregone conclusion:

People visited spectacles like the 1939 World's Fair in New York to be swept up in the excitement of it all. There were no pavilions to solicit the public's suggestions about emerging devices, systems, or role definitions. As millions of visitors strolled through the fair, they learned how to orient themselves to changes in living that seemed to have their own undeniable trajectory. (Winner, 1996, p. 67)

By presenting a particular vision of the future as inevitable and nonnegotiable, the spectacle of the Fair defused any public criticism that might emerge from people

who saw this future as threatening their livelihoods, values, or traditions. The spectacular version of the future on display also helped undermine the possibility that other individuals and groups might have a say in that future design, or offer alternative visions worthy of consideration.

The aim of this volume is to promote a more open and inclusive discussion of the future possibilities for media and media studies, challenging rather than participating in dominant tendencies to lay claim to a particular future. The book draws together leading and emerging scholars in the field of communication and media studies to address, directly or by default, the problem of how to study and make sense of media at the current conjuncture. The chapters are not meant to be prophesizing so much as provisional and exploratory. They highlight some of the major challenges and opportunities facing scholars, students, activists, and other parties concerned with understanding our changing media forms and environments, and realizing their more democratic possibilities. Some authors advocate for paradigm shifts in the field of media studies, while others take more targeted approaches, focusing on specific industrial, technological, or cultural contexts. The essays are grouped into seven sections: (1) theory, methods, and pedagogy; (2) social and mobile media; (3) media industries and infrastructures; (4) journalism and media policy; (5) interactivity, affect, and media subjectivities; (6) children and youth cultures; and (7) sustainability. There are many themes and conversations that cut across these sections, and many other possible ways that the work could be subdivided – around issues of time and space, labor and work, materiality and immateriality, convergence and remediation, access and inequality, to name a few. Before explaining the chosen subdivisions in more detail, it will be helpful to first consider what we mean by “media” in a world where media are virtually everywhere.

Defining the Media in Media Studies

One central question for both the present and future of media studies concerns the very definition of media: what counts as media now that it no longer makes sense to limit the term to film, television, audio, and print? Does it still make sense to refer to a broad concept or category of “media”? If the more appropriate terms are “digital media” or “new media,” then what do *these* terms encompass? Terms like “convergence,” “remediation,” “interactivity,” and “user-generated content” capture a general sense of current transformations, but what are some productive ways of parsing out the varied meanings and phenomena that these terms invoke?

Jonathan Sterne (2007) makes an important distinction with respect to “new” media. Most people typically think of computers and digital media forms as new media, in contrast to earlier analog forms. But in reality, digital computers have been around for decades. “In a weird, recursive way, new media are ‘new’ primarily with reference to themselves,” writes Sterne. “Today, computer and other digital hardware

displace their own counterparts more than anything else” (p. 19). Sterne suggests that we distinguish two models of “newness” in relation to media change: “(1) the ‘newness’ of a medium with respect to other media, and (2) the so-called state of the art in design and function *within* a given medium” (p. 18). For example, the Apple iPad and a host of also-ran digital tablets currently count as the newest in new media. But even the iPad, released in April 2010, is not really brand new anymore. What is new is each new model that Apple releases, which renders the earlier versions stylistically obsolete. Although a seemingly smart business model, this approach requires Apple and its competitors to negotiate a precarious balancing act, lest even the most avid of early adopters begin to suffer from newness fatigue. After all, how many new devices can people buy before newness itself begins to seem old?

As Sterne’s distinction between these two models of “newness” suggests, media studies needs to be careful to avoid reifying the concept of “new” media. Not only can “new” mean different things, but what we call “conventional media” remain important and relevant, not only as objects for historical comparison but also as institutions and technological forms with their own – albeit uncertain and indeterminate – futures. The media most often singled out in this regard are books, newspapers, and television. We hear a lot about the imminent obsolescence of paper bound books these days; nevertheless, more printed books continue to be produced each year than the year before. As Harvard librarian Robert Darnton (2010) has noted, “I have been invited to so many conferences on ‘The Death of the Book’ that I suspect it is very much alive” (p. 22). This is not to suggest that the business of book publishing is flourishing, or that libraries have nothing to worry about. But there is a reason why Google is expending so much energy on the digitization of bound books (one imagines a small army of manual labor). For their part, newspapers also are clearly in trouble, but the *New York Times* still has 50 times the number of newsroom employees as the online-only *Huffington Post* (Alterman, 2008). One suspects that if and when the professional writing dries up, business ventures that now rely on “immaterial labor,” or labor paid for with someone else’s dime, will realize that the best writers and reporters are the ones who do it for a living.

Just as Darnton is skeptical about the death of the book, others likewise find rumors about the death of television to be greatly exaggerated. While many people now watch television shows on their computers and other devices instead of their television sets, alternative modes of reception do not mean that TV *per se* is disappearing. “TV still dominates as a mode of production, distribution, and reception of the very genres that it helped create,” notes Toby Miller (2011). “Time-shifting and platform choice are versions of what has long been the dominant norm – watching material produced and bought by television networks” (Miller, 2011). In fact, the loudest claims about the death of broadcasting in the early 2000s came from mobile network operators competing for a share of the television market, as Max Dawson shows in his contribution to this volume. The mobile industry players portrayed broadcasters as irrelevant and outdated in order to position themselves as the proper custodians of the broadcast spectrum. In her chapter, Lisa Parks likewise emphasizes that the analog spectrum is not a relic of the past but instead contested terrain for

the future of media, a fact that clearly runs counter to prevailing assertions about the digital TV transition.

In short, in order to avoid reifying the “new” in “new media,” media studies needs to steer clear of echoing industry rhetoric on the distinction between new and old. Our research agendas need to avoid celebrating recent innovations as radically different and inherently better, and instead engage in forms of analysis that offer more nuanced insights about the relationship between technological change and social change. It is certainly worthwhile to start with new media forms and consider how older media fit into their genealogies. But it is likewise productive to consider what the emergence of new media forms tells us about the meaning and experience of existing media. A telephone only becomes a “landline,” for example, when comparing it to newer and more mobile versions of telephony. In other words, the new level of mobility afforded by and designed into networked digital devices helps us think anew about the situated, localized character of wired, over-distance communication. In fact, the way new communicative devices are integrated into our lives gives us cause to revisit the most basic and fascinating forms of face-to-face “interactivity.” This is not to suggest that we should view the past through the lens of the present. Instead, we need to recognize the deeply embedded ways that the past is still with us in the present. Further, understanding the shape of things in the *past* provides a better purchase on the shape of things in the *present*, and lessons learned from the past, even if learned in painstaking ways, provide invaluable guides for the future.

Mark Coté’s contribution to this volume provides a noteworthy example. Coté looks to the very distant past (and those who study it) for insights about the forms of mobility and sociality enabled by new location-aware technologies. He asks what we can learn about our location-aware online activities via “a prehistoric turn,” considering a moment in Paleolithic time when the very possibility of being human emerged in interaction with stone tools. From the *very beginning* of human experience, a direct, constitutive relationship took shape between what was distinctively human activity and the development and use of technologies. It may seem like a stretch to compare a rudimentary stone tool to a digital media device, but such tools did in fact mediate humans’ relationship with their environment, conceivably providing a way for users to view themselves as actively engaged with their surroundings and conditions of existence. (Of course, they probably didn’t think about it exactly in these terms, not yet having the language to do so.)

It is not necessary to go back as far as Coté does to gain insights about the media forms and practices that appear new today. Lev Manovich has an especially keen eye for identifying the revival of earlier dimensions of media in newer digital forms. In “What is Digital Cinema?” he notes how the first version of QuickTime bore a striking resemblance to Edison’s nineteenth-century Kinetoscope, for example (Manovich, 1995).¹ Both viewing devices were capable of displaying only very short motion pictures, played on a loop in a tiny frame suitable for only one viewer at a time. To insist on the newness of QuickTime when it was introduced in 1991 was to overlook the way it revisited an earlier moment of motion picture display – a moment characterized by the *convergence* of photography, animation techniques, live vaudeville

acts, and urban commercial amusements. Further, to see QuickTime as somehow superior or more sophisticated than the Kinetoscope risks being seduced by the digital sublime. Nor does it make sense to draw a linear path from the earlier form to the latter, as if one innovation inevitably led to the other. Why would a linear, advancing path of technological progress lead to such a similar form a hundred years later?

A question very much tied to debates about the so-called death of old media concerns the relevancy of “old” media studies. How useful are the concepts, theories, and methodologies developed in the days before the rise of the Internet and digital media for understanding the new media landscape? For some, the answer is not useful at all: everything about media studies before the Internet is tired, outdated, and inadequate, best left as a pile of historical detritus in the trash heap with printed books and newspapers, celluloid film, and analog televisions. In their contribution to this volume, Geert Lovink and Ned Rossiter are adamant that conventional film and media studies – especially the old emphasis on visual representations – make no sense for studying social, mobile, and real-time interactive media. For them, the overreliance on outmoded theory has led media studies down a dark path of conceptual stagnation, and the field now suffers from an incapacity to make sense of the social and interactive dynamics of the digital networked realm – a distinct sphere that demands its own theory and methods.

Whether one finds established media theory and method useful or not, media studies cannot escape the brute fact that digitization and computerization have upended the field’s objects of analysis, seriously complicating what exactly “media” is. How does one study “media” when media are so many different things? As a set of social and technological processes, the proliferation of networked digital media is related in complicated ways to changes in forms of social organization, communication, human identity, and subjectivity, and media studies needs to find ways of making sense of how this is happening and what it means. Still, I would suggest that digital media studies should avoid creating a straw man out of the analysis of visual representation characteristic of a particular segment of scholarship, especially when the broader field has long drawn on a wide range of approaches beyond semiotics and textual analysis. If scholars were to divorce themselves entirely from earlier media and established theory and method in media studies – if that were even possible – vital comparative perspectives would be lost, and along with them a host of potentially valuable insights, not only on the past but also on the range of future possibilities.

Part 1: The Future of Media Studies: Theory, Method, Pedagogy

Part 1 of this volume contains essays that address some of the major theoretical, methodological, and pedagogical issues of critical concern for the future of media

studies. If the field is going to have a future at all, what should that future look like? What are the questions that need to be raised and addressed in order to situate the field in a position of relevancy and vitality, as a living, breathing space of new and compelling ideas and interventions? Although the six chapters collected in this section by no means exhaust the range of perspectives, taken together they provide productive points of departure. What these authors share in common is a strong conviction that theory, research, and pedagogy on the new media landscape must be radically rethought in ways that either substantively build upon or depart substantially from established approaches to studying conventional media. Networked digital media penetrate virtually every sphere of social life, and the challenge of media studies is to make sense of mediated environments in ways that matter.

Importantly, each author in Part 1 reflects on the intellectual labor and experiences of media studies scholars. Each proposes particular ways that people who study the media might reinvent approaches to their work – especially their research, writing, and pedagogy – thereby reinvigorating their thinking and transforming media studies from the inside out. Who should we take ourselves to be, as theorists, researchers, writers, and teachers, as well as producers, consumers, or users of media ourselves? How do media studies scholars go about inventing new and useful concepts to explain distributed, networked media environments? Collaboration seems critically necessary, advocated by nearly everyone, but how should collaborative research take shape? What are the terms of entry for collaboration, and when and how do academic researchers collaborate with non-academics? Given the conservative disciplinary structure of academic institutions, is the academy in fact the wrong place to try to do innovative and relevant work? And if not there, then where? What sort of institutional spaces do members of the media studies world need to construct for themselves, and where will they find the resources to do so?

Geert Lovink and Ned Rossiter raise many of these questions in the two chapters that open this volume, provocatively arguing that the field of media studies has yet to develop a theory of *itself*. Audience studies investigated fandom and the production of meaning, textual analysis preoccupied itself with signification processes attached to content, and political economy turned its gaze on institutional power. Medium theory, while close to these authors' own interests, still falls short as they see it, because it established a continuum between old and new media without considering how media forms themselves can give rise to the production of new concepts. In their view, media studies desperately needs new concept production, born out of both online and offline collaborative efforts. To develop new concepts, media researchers should begin with reflexive mediation, examining how they use their objects of study in the research methodology itself. They insist on the need for nonrepresentational analysis – moving the agenda beyond the analysis of visual representation to mobile media, miniaturization, smart technologies, and the integration of media into urban environments.

Changes in media brought on by distributed digital networks and their associated institutions, devices, and practices present particular challenges and opportunities for

media studies education. The challenges are formidable, as anyone trying to teach in the field of media studies senses intuitively. The problems are often defined as generational, since many students live, work, and play in more immersive, or at least very different, media environments than their teachers. But the pedagogical challenges go beyond age differences, extending all the way to the structural changes that are wrenching higher education and dismantling the social contract it once offered to the middle class. As David Noble has noted, technological changes in higher education are deeply tied to its privatization and commercialization, with technology functioning as both “a vehicle and a disarming disguise” (Noble, 2003, p. 26). While new technologies provide tools for collaborative learning and distance education, these new pedagogical models have placed a considerable strain on an already stressed system of higher education. Debates over the relative merits of online learning, open courseware, and other new instructional technologies are far from resolved. What new approaches do we need for teaching not only *about* but also *with* digital media? What forms of media literacy are most important for students growing up in hyper-mediated environments? How much should media studies curricula be given over to instruction in practical media production skills and web design, or, for that matter, computer science and software engineering?

Alexandra Juhasz’s contribution to this volume addresses some of these pedagogical issues, offering an analysis of her own hands-on effort to teach about, and literally *on*, YouTube – an experiment she began in 2007 at Pfizer College in California. Since there was essentially no academic writing about YouTube at the time, and since the purpose was to explore the possibilities and limitations of the YouTube platform, Juhasz stipulated that all the material for the course would come from YouTube itself. Her chapter highlights a few of the sometimes exciting, sometimes painful results of this experiment.

Juhasz’s chapter also offers valuable insights on transformations taking place in writing and publishing in media studies. Her experience teaching a course on YouTube, which she repeated in 2008 and 2010, in turn became a research, writing, and publishing experiment. Juhasz published *Learning from YouTube* as a born-digital “video-book” with MIT Press. As a series of “re-posted” blog entries that she wrote while engaging in these activities, interspersed with her reflections about the experience after-the-fact, the printed chapter itself enacts the messy process of mediation from print to digital and back again.

Contributors to Part 1 also address the formidable questions of methodology raised by the emergence of new media forms and infrastructures, and the multiple levels of convergence that define the media landscape. What sorts of new methodologies will need to be devised to analyze this changing landscape? The sheer quantity of media available seems to overwhelm the possibility of conducting effective studies that can be generalized beyond very limited contexts. People with adequate connectivity have access to a dizzying array of media forms and content.

In his contribution, Lev Manovich offers his vision for a new methodological approach that will allow for the management of precisely this problem of media

quantity. The methodology he proposes – called “media visualization” – is designed for analyzing large collections of visual data. Where *information* visualization involves translating the world into numbers and then visualizing the relationships between those numbers, *media* visualization involves translating a set of images into another image – one that can reveal patterns that might not otherwise be apparent. Using open source image processing software normally used in medical research and other scientific fields, Manovich and his collaborators have designed a set of tools for media visualization that can be used by other researchers interested in exploring large sets of images.

Focusing on the future of digital game studies, Mia Consalvo also considers the problem of methodology at length. New methods are needed, as the digital game industry has evolved at a phenomenal rate. Game studies can no longer consider console games or the Western market as its primary areas of focus. Social games, casual games, virtual worlds, indie games, and online games all expand the boundaries of what count as games. In addition, markets such as those in China and Korea, and game development companies in Southeast Asia and Eastern Europe, are challenging the dominance of Western and Japanese firms. How is game studies responding to such changes? How is the field coalescing, now that there are dedicated journals, book series, conferences, and academic programs spread around the globe? Consalvo surveys how game studies scholarship has evolved, what approaches have become dominant, and what views have emerged about the “proper” way to do game studies research.

Many regions of the world are unrepresented in the work collected in this volume, a problem that reflects and reproduces one of the most difficult problems haunting media studies, and one that must play centrally going forward: the dominance of the Global North in defining the field and its priorities. This problem is deeply tied to the intractable problem of *unequal access*. The term “digital divide,” coined in the 1990s, remains an apt metaphor for capturing a variety of inequalities that continue to define the digital media landscape at all levels, from the global to the local. Latin American and other scholars in the developing parts of the world have never enjoyed the privilege of losing sight of this problem. As Raúl Trejo Delarbre shows in his contribution, most Latin American Internet researchers have tried to navigate a middle ground between bleak prognostications about ingrained and exacerbating inequalities on the one hand, and overly optimistic claims about the radical potential of the Internet to alleviate inequality on the other. In reality, issues of access are often complex and multifaceted, as suggested by the spread of Internet cafés and other sites of public access to the Internet in Latin American countries. The overall picture of digital media access across Latin America and other developing regions is not easy to measure, complicated as it is by patchwork efforts at the local and national levels, on the part of both public and private actors, to “connect” those who remain unconnected. Still, it remains true that the benefits of the digital economy have not been equally bestowed. Euphoric promises made about the Internet’s potential to eradicate inequalities have proven profoundly off the mark.

Part 2: Social and Mobile Media Futures

As little as 20 years ago, it would have been hard to predict the rapid emergence of social media phenomena like Facebook and YouTube, or the lightning-speed global diffusion of mobile systems and devices. Part 2 of *Media Studies Futures* takes up some of the issues and topics of concern to the present and future of *social and mobile media*. While “social media” are usually understood to refer to web-based platforms like Facebook, Twitter, and YouTube, and “mobile media” to iPhones, Droids, and other branded and networked devices that people carry with them everywhere they go, in fact this distinction is a tenuous one, as the chapters in this section suggest. Our own daily experiences with social and mobile media are themselves rife with blurry distinctions – between sociality and mobility, work and play, public and private, online and off. As I sit here working in a coffee shop, I can access Facebook and any number of other online social media platforms from either my computer or my mobile phone. Although only the smartphone has an embedded location-sensing device that can automatically pinpoint where I am, I could easily “check in” on my computer if I felt like letting my nearly 300 Facebook “friends” know my whereabouts.

Location awareness is not only about being social or communicating with “friends.” Our varied uses of these platforms also generate valuable data about our behaviors and preferences, to be analyzed by an increasingly ubiquitous and sophisticated market research surveillance apparatus. Strangely enough, this fact does not seem to prevent Facebook’s hundreds of millions of users from continuing to log on and disclose their private activities on a regular basis. Especially among younger users, there seems to be a decided lack of concern, or at most ambivalence, about the semi-public display of private life, or the impact that public display might have on their future lives. Nor do many of us who pass our time on social network sites (young or old) seem all that concerned about whether the hours we spend there count as labor or leisure. In light of the significant social implications of these blurring boundaries, it seems relevant to question what it is that attracts people to hours of social and mobile media use. Indeed, it seems as important to ask how today’s social and mobile media orient users toward the future as it is to consider what the future of these current new media forms might be.

The literature on social and mobile media can be subdivided in myriad ways, but it is hard to bypass one major division between research that focuses on users and uses from an ethnographic perspective, and work that attends to the institutional, technological, and political-economic dimensions of social and mobile media systems. Where scholars like danah boyd (2007) are primarily concerned with user experiences and forms of interaction in online social networks, for example, scholars like Mark Andrejevic (2007) are instead concerned with the forms of institutional and peer-to-peer surveillance that mobile devices and online social network platforms enable. Still, work that falls on either side of this divide is admittedly wide ranging, and there is certainly much work that does not fit neatly into either “camp.” Andrejevic’s analy-

sis of peer-to-peer or lateral surveillance can certainly be classified as a study of uses. And even Henry Jenkins's *Convergence Culture* (2006), which celebrates the forms of user empowerment that new media afford, does not ignore entirely the role of media corporations and their economic interests. Nevertheless the divide is apparent: where Jenkins sees a "participatory culture," Andrejevic sees a "digital enclosure."

The chapters in Part 2 of this volume represent work that straddles the divide between users and infrastructures, participation and enclosure. In his contribution, Mark Coté examines the forms of sociality and mobility afforded by digital networked media and new location-aware technologies by drawing on Italian autonomism and its central concept of "immaterial labor."² Coté aims to recover our online social media activities from their capitalist appropriation, at least for a moment, so that the creative and constructive capacities of these activities can be better understood. In fact, Coté writes, in the activities of online social networks we can see very clearly what Marx insisted all along – that commodities are always born of social relations. The practice of "checking in" via social media platforms like Yelp or Facebook Places generates informational commodities of special value in a digital economy, providing a rather transparent example of the way capitalism continues to parasitically sustain itself by colonizing what are essentially *social* activities. Such activities, whether taking place online or off, push beyond the boundaries of what capitalism is capable of subsuming.

Adriana de Souza e Silva and Eric Gordon likewise examine the rise of location-based networked services, exploring ambivalent user attitudes toward these technologies. Although many people are concerned about the extent to which location-based services enable institutions to track their movements and whereabouts, these services also provide us with a sense of awareness and control over the spaces we move through and occupy. The fact that location-aware systems can be used for these different, seemingly cross-purposes points to the new forms of "differential mobility" they enable, enhancing mobility for some while immobilizing others (Wood & Graham, 2005). New media devices and their infrastructures are reconfiguring how people move through and experience their spatial environments, shaping in complicated ways the social construction of space and the variable levels of control individuals have over their movements and surroundings.

In her chapter on changing models of public health communication about pandemics, Lisa Cartwright shifts the focus from *locality* to *temporality* as a key dimension of social media and their uses. What the 2009 "swine flu" campaign made clear was that "the days of using the pamphlet, the billboard, and the television public service announcement as primary means of health communication were over." Cartwright traces the viral social mediation of the H1N1 pandemic, showing how the fearful possibility of imminent disease threat that the virus presented – the possibility of a rapid viral "outbreak" – was well suited to the temporal mode of social media. The emerging, social media-based paradigm of public health communication is built on strategies of anticipatory surveillance and preemptive mediation, favoring a logic of emergency and rapid emergence. Unfortunately, Cartwright explains, such an

approach renders invisible other deadly disease epidemics, such as Hepatitis C, that unfold in bodies and populations at a much slower pace. Like other contributors to this volume, Cartwright's chapter highlights the inescapable fact that the material world of bodies and other living organisms still matters, interacting in complicated ways with the hardware and software of social media. The uses of social media are situated, embodied practices.

While common assumptions hold that the significant innovations leading to the rise of social and mobile media were born in places like Harvard dorm rooms, in fact this represents a decidedly narrow view of innovation and the dynamics of the global digital economy. Too often, the contributions of vast swaths of the planet have gone largely ignored. Even astute insights about the role of immaterial labor in the digital economy assume a level of connectivity – as well as a mode and amount of leisure time – that most of the world's inhabitants do not enjoy. In their contribution to this volume, Cara Wallis, Jack Linchuan Qiu, and Rich Ling focus on grassroots forms of innovation found in the developing world – local practices that have been instrumental to the global diffusion of mobile devices and infrastructures. With a special emphasis on China, they examine alternative economies of mobile phone use, manufacture, service, and repair – very *material* forms of labor – that have emerged in the Global South. The information have-less engage in what the authors call “subsistence tinkering,” devising their own technical means of enhancing the functionality and prolonging the life of mobile handsets. These tinkering practices represent a new level of flexible manufacturing, as an alternative mobile handset culture arises out of the necessity and ingenuity of those who might otherwise fall on the unconnected side of the digital divide.

Part 3: Media Industry and Infrastructure Futures

Nothing demonstrates the transformations that have wrenched the media industries over the last several decades better than the fate of the recording industry, an object of analysis unfortunately unrepresented in this volume. One would be hard-pressed to make a case for this industry's bright future, which is not to suggest that the situation is completely hopeless for music and musicians. The hardship that the recording industry has suffered has been arguably beneficial in some ways for the music world, at least for live music and for avid listeners with good connectivity. Full of wins for some and losses for others, the case of the recording industry, while unique in many respects, nonetheless underscores the profound changes that have occurred in the media industries and their infrastructures along with the rollout of digital media and distributed networks. Part 3 of *Media Studies Futures* draws attention to these media industry and infrastructural changes, as well as changes in the broader economy (in Greg Elmer and Andy Opel's contribution), as objects of vital concern to media studies. Although these chapters focus largely on the US context, they nevertheless lay out some vital issues of global relevance.

While the idea of convergence is typically used to refer to the merging of one or more media technologies, like television and the World Wide Web, it also applies at the level of industry and infrastructure, with the same number of caveats and complications. Among media and IT industry stakeholders, one finds a complex picture of interests and strategies that converge one minute and conflict the next. As Dan Schiller (2007) has argued, although it is often claimed that media convergence occurs “through intrinsic technological imperative,” in reality it stems from a combination of industry strategy, public policy, and directed developments in science and technology (p. 103). Among the most powerful forces shaping and accelerating the convergence of different media are the conflicts and negotiations hashed out in the media and IT industries, along with a host of decisions about infrastructures and their regulation that are typically made by engineers and policymakers with little or no public input.

For its part, the commercial film industry is undergoing a makeover at all levels, from production to distribution to exhibition. The transition to digital cinema has been far from a simple matter of designing more sophisticated special effects. In his contribution to this volume, Charles Acland discusses the future of cinema through the career of filmmaker and “technological auteur” James Cameron. Holding the distinction of producing and directing the two top-grossing films of all time to date, Cameron is widely seen as the embodiment of success in the Hollywood film industry. Although no filmmaker works alone, Cameron receives wide recognition for making a major, single-handed impact on the technological and aesthetic trajectory of commercial cinema. For Acland, Cameron’s film career, oeuvre, and obsession with pushing the technological limits of film provide an avenue to understanding the dynamics and directions of the cinema industry. While Cameron is famous for his “game-changing” films like *Avatar*, Acland argues that it is also necessary to consider the way he has used his documentary projects as instruments for promoting particular directions in the development of film technology. In the projects and persona of James Cameron, Acland argues, we find the technological imperative that guides the future of cinema.

If the transition to digital cinema requires careful analysis of the changing dynamics of the film industry, the transition from analog to digital television is another major “infrastructural changeover” that demands the attention of the field. In her contribution to this volume, Lisa Parks examines this changeover, emphasizing the importance of studying media infrastructures, in all their physicality and unsightliness, for what they reveal about “issues of materiality, distribution, environment, visualization, and social power.” Although often overlooked and impossible to study in their entirety, media and IT infrastructures provide the basis for the very possibility and functionality of the mediated environments we inhabit. Parks looks at the ways that various actors – government agencies, trade, and community organizations – communicated with the public in an effort to prepare them for the infrastructural transition in the United States, and how these efforts gave citizens cause to consider where their television signals come from, who owns and controls them, and the policies that regulate them. The public education and converter-box coupon campaigns also brought to the surface the

socioeconomic disparities and uneven geographies of the digital TV transition, especially in the ways these campaigns addressed fixed-income and minority communities.

Max Dawson's contribution brings mobile media into the analysis of television industry and infrastructural changes, focusing on the institutional conflicts between broadcasters and mobile network operators over control of mobile television. During the early 2000s, both broadcasters and mobile communications companies put mobile television at the center of the agenda for their respective industries' futures. Although they initially pursued diverging paths for mobile television provision, their industry strategies eventually collided. While they continued to utilize different transmission and reception technologies, the business model and user experience that each offered shared too much in common for either industry's comfort. Here Dawson uses Bolter and Grusin's (1999) concept of remediation to explain not only the *technological* changes in television, but also the refashioning of television's *protocols* broadly defined, including its uses, business models, contents, regulations, and cultural meanings. While the industries have now moved on from this confrontation, Dawson argues, "mobile television was for broadcasters and mobile companies a proxy battle in the much larger war over spectrum and policy concessions." Battles over the future of media convergences will play out in precisely these spaces where once-established institutional boundaries are crossed.

Greg Elmer and Andy Opel's contribution is a departure from the other chapters in this section but nevertheless speaks to the dynamics of industries and their relevance to the future of media studies, in this case addressing how the future is *premediated* in the logic of financialization. Building on Richard Grusin's (2010) notion of *premediation* and James Carey's analysis of the way the telegraph invented the future as a new domain of market activity, Elmer and Opel examine the future-orientation of the financial markets and the extension of the logic of futures markets to other domains of social life. Like Lisa Cartwright's analysis of the temporal dimensions of social media and disease pandemics, they bring to the fore issues of temporality and prediction, the "anticipatory mediation" (Cartwright's term) that permeates networked digital culture. Like Lovink and Rossiter, they call for nonrepresentational media studies – for them, conventional representational analysis is ill-equipped to make sense of data-intensive mechanisms like futures markets, which aim to bypass conventional forms of signification and to "actively discredit political forms of representation." Elmer and Opel's chapter offers an innovative and compelling approach to understanding media temporality, the financial logic permeating politics, and the reorientation of subjective action around futures and speculation.

Part 4: Journalism and Media Policy Futures

In prevailing assessments of the winners and losers in the digital economy, there is one victim that may be suffering worse than the recording industry. In the race to

obsolescence, the US newspaper seems to be eclipsing all other “old” media. In a *New Yorker* profile on “the death and life of the American newspaper,” Eric Alterman (2008) recounts an episode of *The Simpsons* in which a cartoon version of Dan Rather introduces a debate panel featuring “Ron Lehar, a print journalist from the *Washington Post*.” Heckling the panelists, Bart’s bully-turned-friend Nelson Muntz shouts out, “Haw Haw! Your medium is dying!” Principal Skinner proceeds to admonish him for the outburst, but Alterman insists that Nelson is right: “Newspapers are dying; the evidence of diminishment in economic vitality, editorial quality, depth, and over-all number of papers is everywhere.” While the Internet offers an endless stream of blogs covering every topic imaginable, the replacement of underwritten professional journalism with the free labor of amateur writers and wisdom-of-the-crowd reporting marks a turn of vital concern to the future of media and media studies.

The US newspaper and its journalism profession are in a great deal of trouble. However, as scholars studying this issue carefully insist, it is not necessarily the Internet’s fault. Just as not everyone agrees that file sharing is entirely to blame for the recording industry’s woes, not everyone sees the rise of the blogosphere or Craigslist as the principal culprits of the newspaper crisis. Robert McChesney and John Nichols (2010) in particular argue that neither the Internet nor the financial crisis is the major cause of the steep decline in the status and viability of US newspapers. Instead, these factors have accelerated a process that dates to the 1970s, when corporate ownership and consolidation of newspapers began in earnest. “Go back and read a daily newspaper published in a medium-size American city in the 1960s,” they note, “and you will be awed by the rich mix of international, national and local news coverage and by the frequency with which ‘outsiders’ – civil rights campaigners, antiwar activists and consumer advocates like Ralph Nader – ended up on the front page” (p. 32). While it is nice to think that we can find a similar rich mix of coverage and perspectives online, since after all we have the whole World Wide Web at our fingertips, there are big questions about whether the Internet is really filling the void left by the disintegrating newspaper press, especially at the local level.

The three chapters in Part 4 address various dimensions of the crisis in journalism in the United States, calling for a variety of measures to repair the problem. Two of the contributors are based in the United States and write about the US context. Martin Eide, from the University of Bergen, Norway, focuses largely on the institution of journalism in the US context as well, but briefly considers it in comparison to the Scandinavian “Democratic Corporatist” model.

In his contribution, Richard Campbell examines the resurgence of partisanship in the US press, seeing it as essentially a reflection and response to market forces. For the news media, muting political leanings to reach a mass audience makes no sense when such an audience no longer exists. (See Jack Bratich’s contribution to this volume.) Instead, media organizations see more money to be made by targeting and catering to niche markets, including those based on partisan allegiances. In this new partisan marketplace for news, we see the decline of the “objective” ideal in US journalism that dominated throughout the twentieth century. The new era of

partisan news – also called the “journalism of assertion” – is marked by the deterioration of the “journalism of verification,” which kept watch over the state and private institutions in the era of nonpartisan reporting. In order to recover the democratic role of the press, Campbell argues, journalism needs to reinvigorate the “news of verification” and develop livelier alternatives to the static formulas of reporting characteristic of commercial television news and the nonpartisan press.

For Martin Eide, an essential challenge for journalism studies – in a time when the phenomenon and concept of journalism is more contested than ever before – is the question of journalistic agency. To explore this question, Eide argues, journalism studies can find useful insights in scholarly work on the problematic of structuring. While some argue that journalism is an activity that anyone with an Internet connection can engage in, Eide defends the institutional perspective: the view that journalism is not just an activity but an institution with a vital role to play in democratic governance, and thus one that requires professional training and full-time jobs. The institution of journalism clearly has an important history, Eide maintains, and it is the *institution* that must be conceived as having a viable future. In short, for journalists to be accountable to the publics they serve, they need to have agency, and in order to have agency they need institutional support.

In his chapter, Victor Pickard places the crisis in journalism in the broader context of media policy, arguing for a more active role for media studies in media policy debates and policymaking. By situating this gap between media studies and media policy within historical, intellectual, and ideological contexts, he proposes possible strategies for bridging the two areas. He addresses some of the challenges and opportunities for scholars to intervene in core media policy debates in the coming years, including discussions about the future of journalism, media ownership, public media, and Internet policies like Net Neutrality. According to Pickard, media studies and communication scholars have a special role to play in helping to advance policy that enables greater democratic potentials for all of society.

Part 5: Interactivity, Affect, and the Future of Media Subjectivities

In his essay “Who Will We Be in Cyberspace?” Langdon Winner (1996) notes that, as society invents new technologies, it also invents and reinvents people: “To invent a new technology requires that (in some way or another) society also invents the kinds of people who will use it; older practices, relationships, and ways of defining people’s identities fall by the wayside; new practices, relationships, and identities take root” (p. 64). The situation is of course more complicated than this, since we also design new technologies in order to help us do particular things and be particular kinds of people, and since these changes play out in unpredictable ways, with plenty of unintended consequences. But it nonetheless holds true that human beings are in

some ways invented and reinvented along with the invention of new technologies. We had to learn to become people who drive cars, type on keyboards, and take photographs, to name a few examples, and these devices have contributed to major changes in our ways of life and who we take ourselves to be.

In the domain of personal photography, certain human beings began documenting their lives in images around the turn of the previous century. Many of us now have cameras that we carry around wherever we go, and those cameras are connected to telecommunications networks that allow us to share the images with other people. We do this either in semi-public mode, as on Facebook or Flickr, or person-to-person, as when we text images to others in order to share particular moments or experiences. Much of this image-sharing behavior is utterly banal, like the photographs people take of food and flowers and other mundane things they encounter in their daily lives. But these banal moments of digital media use matter. They speak to the formation of media subjectivities, how we use media technologies to organize our lives, and how the forms they take can offer either productive possibilities or more limiting constraints, or often both at the same time.

This tension between autonomy and constraint raises an important issue concerning the prevailing model of media device and software development embodied in popular devices like the iPhone and the iPad – that is, the relative merits of their closed form with respect to issues of user agency. Jonathan Zittrain (2008) refers to the closed, proprietary form of device and network design as the “appliance model,” which he contrasts with the more open and “generative model” of early PCs and Internet development. Software code gives devices like the iPad their functionality, and the closed model of design makes them especially user friendly and reliable. However, these nicely functioning devices assume a particular kind of user and form of media subjectivity. Specifically, they do not encourage users to know anything about the underlying code that supports their functionality, or to participate in the development of that code, other than in indirect and circumscribed ways. There are of course open source alternatives, but only a very small percentage of people on the planet have the skills necessary to program their own devices.

Part 5 addresses a set of issues of central concern to the future of media studies: the invention of new media subjectivities. Opening the discussion, Jack Bratich considers the crisis of “the audience” and its radical renegotiation in the interregnum – the moment of transition that “the people formerly known as the audience” now precariously occupy. He asks: how are media subjects brought into being, rendered knowable, and made into objects of intervention? To address this question, Bratich argues, the field of media studies needs to revisit and reopen earlier ways of conceptualizing and problematizing the audience: masses and publics, consumers, receivers, spectators, social identities, active audiences (decoders), and fans. In his analysis of the audience, we again encounter Italian autonomism and the attempt to theorize social and creative activities as they push beyond and otherwise avoid being fully captured by capital. From a Deleuzian perspective, there is no predicting what will happen when bodies mingle together and engage in affective relations with one

another. Bratich proposes the concept of “interactivism” as a way of rethinking media subjectivities post-audience, where bodies interact and form collectivities through new modes of interaction, both actual and virtual.

Karin Wahl-Jorgensen is likewise concerned with rethinking the concepts used to define collectivities – in this case *the public* and mediated public participation. She calls for more attention to emotion as a mobilizing force in politics, compensating for what she sees as a profound “epistemological deficit” in political communication research. Surveying some of the work that is already beginning to fill in this theoretical gap, she explains how the rational, dispassionate citizen at the heart of liberal democratic theory is being radically rethought, as the affective turn in cultural studies and the humanities spills over into the social sciences, and into political science in particular. Especially for scholars studying social movements, the question of affective engagements in politics has become a central concern. Drawing on the distinction Brian Massumi (2002) makes between emotion and affect, Wahl-Jorgensen argues that conceptualizing emotion as the narrativized interpretation of affective experience enables a better understanding of its deeply politicized and politicizing dimensions. And although emotion can have destructive political consequences, Wahl-Jorgensen explains, it also has integrative possibilities and enables the empathy necessary for more diplomatic forms of political deliberation.

David Golumbia offers another vital contribution to the discussion of new media subjectivities, focusing on the operations of computationalist ideology – the view that everything in reality is ultimately made up of computation. As noted earlier, this ideology is found in crystallized form in the work of Ray Kurzweil. Golumbia provides a thorough vetting of Kurzweil’s ideas, including his version of the “uploading” story, or the familiar trope that human beings are on the verge of transcending embodied existence and migrating into a world where human minds become computers that inhabit realities much like those seen in videogames. According to Golumbia, works of science fiction like *Dollhouse*, *Battlestar Galactica*, and *Gamer* demonstrate the conceptual flaws in the uploading story. Specifically, they show how ideas about the technological transcendence of material, bodily constraints rely not on actual advances in science and technology, but on distortions beyond any recognizable limits of our conceptions of the human, the mind, and the body.

In the penultimate chapter in Part 5, Lisa Nakamura makes an important contribution to her own groundbreaking work on the forms that race and racism take online, this time through an analysis of player speech in multi-user online games. “Trash talk” is a regular part of interaction in multi-user online games, and at times it can take virulently racist and sexist forms. Whether that sort of talk should *matter* has been an object of debate among players. As Nakamura shows, many players are expressing a growing resistance to this culture. Her chapter looks at born-digital media campaigns against racism, sexism, and homophobia including blogs, YouTube videos, and other web-based media, examining how they document, archive, and critique instances of racism, sexism, and homophobia in live gameplay as well as within the texts of games themselves.

Finally, Marisa Brandt's contribution returns to Bratich's question about the ways subjects are brought into being and made objects of intervention along with changes in media forms. Her chapter examines the application of virtual reality (VR) systems as therapeutic tools for treating soldiers with post-traumatic stress disorder (PTSD). VR therapy for PTSD has taken shape in response to a critical contemporary conjuncture: (1) a group of US youth raised on videogames and other types of digital media, (2) who were just sent to fight in violent conflicts, and (3) now represent a new generation of veterans with PTSD. Brandt makes the case for why media studies should be interested in this therapeutic practice: it is being used to intervene on the bodies and psychological lives of affected veterans from Afghanistan and Iraq – members of a generation living through a unique, and uniquely violent and crisis-riven, historical moment. In short, there are reasons why we are seeing the death of the audience, increased attention to affective politics, a preoccupation with the uploading fantasy, racism in online multi-user gameplay, and the emergence of something called "virtual reality exposure therapy" *now*: media are changing, modes of sociality are changing, forms of subjectivation are changing, and human bodies and subjectivities are changing.

Part 6: Whose Future? Children, Youth Cultures, and Digital Media

Children's media use and the role of media in the formation of youth identities and youth cultures are issues that have long been of interest to communication, cultural, and media studies. Perhaps more than any other area of research, this work garners a great deal of attention beyond the walls of academia, among policymakers and the general public. The work has broad interest with good reason. Not only are the lives and well-being of children and youth vital concerns in their own right, but young people's experiences are also a barometer of things to come. In studies of language death, for example, linguists focus on how well children are learning the key pronunciations and components of the language (Crystal, 2000). One indicator that a spoken language may be disappearing can be found when the children of the culture are not fully learning its sound system, failing to pronounce particular phonemes.

Studying the way children and youth use digital media likewise reveals a great deal about profound experiential and cultural changes occurring in societies along with the proliferation of distributed networks and digital devices. (The fact that English is the dominant language on the Internet is suggestive of the significant threat it may be posing to linguistic diversity globally.³) A 2009 survey conducted by the Pew Research Center found that 93% of US teens use the Internet. Of course, this general statistic does not tell us anything about the kinds of activities that teens engage in online, or what kind of connectivity teens from different social groups have. Only 32% of US teens accessed the Internet through cable, according to the

survey, and 10% were still using a dial-up connection (Pew Internet & American Life Project, 2009). Another 11% accessed the Internet using wireless via mobile devices – hardly an adequate substitute for a high-speed wired connection – pointing to what Susan Crawford (2011) refers to as the “new digital divide.” “While we still talk about ‘the’ Internet,” she writes, “we increasingly have two separate access marketplaces: high-speed wired and second-class wireless. High-speed access is a superhighway for those who can afford it, while racial minorities and poorer and rural Americans must make do with a bike path” (Crawford, 2011). Clearly, it is not sufficient to ask only whether children have access to digital media or not, but how they are accessing it, and what effects different levels and types of access have on their lives and their futures.

The Pew Internet and American Life Project does extensive research on children and teens’ use of digital media in the United States. The chapters in Part 6 of this volume examine uses of social and mobile media by children and youth in Latin America, in Australia and Japan, and across the South Asian diasporas.

Virtual communities and online social networks function as forms of visibility, recognition, and social inclusion for many young people in Latin American countries, as Rosalía Winocur and Carolina Aguerre explain in their chapter. They consider how, faced with the difficulties of access to entry in the traditional institutions of Latin America – particularly those related to training, employment, and access to power – young people adopt information and communication technologies (ICTs) in order to create alternative avenues to inclusion. By developing flexible and mobile strategies of ICT use and generating their own informal circuits of inclusion at the margins, young people may find avenues to gain access to the formal channels and privileged spaces of ICTs. In short, these authors argue that the Internet and mobile platforms function as compensatory symbolic substitutes for the lack of real power that these young people have.

In their contribution, Radhika Gajjala and Yeon Ju Oh examine the significant role that digitally produced and circulated media now play in the formation of South Asian diasporas. Their chapter examines the techno-mediation of South Asian diasporas through “machinima,” focusing on several examples of South Asian digital diasporic production. These distinctively South Asian examples of machinima demonstrate how the circulation and remixing of Bollywood media provide nostalgic, affective engagements for diasporic South Asian youth. At the same time, they provide the means through which members of these diasporas perform important cultural labor for the Indian state and culture industries.

Damien Spry, in his chapter on the politics of childhood and mobile media in Australia and Japan, examines public discourses about the increasingly ubiquitous presence of mobile media in the lives of children. Spry analyzes legislative, regulatory, and normative reactions to the apparent risks to children in their exposure to the unregulated, adult worlds of sex, violence, and money, via the use of mobile media. Using case studies from classrooms, courtrooms, and government offices in Australia and Japan, Spry considers the politicization of young people’s mobile media

use, focusing on “childhood” and “new media” as discursive sites where the hopes and fears about future generations are powerfully expressed.

Part 7: What Future? Or, the Unsustainable Present

The final section of *Media Studies Futures* deals with an issue of vital concern not only for the future of media and media studies, but for the future in the broadest sense: the urgency of the global ecological crisis. What we face today in the era of global capitalism is an alarming proliferation of what Anthony Giddens (1999) calls “manufactured risks”: risks resulting not from natural forces external to human activity but from human development itself, especially from the progression of science and technology. While the media are the sites at which environmental issues are debated and made visible on a global scale, the media and IT industries also play their own special role in the manufacture of environmental risks. As Jonathan Sterne (2007) writes, “the entire edifice of new communication technology is a giant trash heap waiting to happen, a monument to the hubris of computing and the peculiar shape of digital capitalism” (p. 17).

While media studies has a track record of examining the structural conditions of media production and consumption, the field has been largely complicit in contributing to the “public secret” of media-generated waste and the ecological impact of the media and IT industries. It has for years analyzed media from many directions but has paid almost no attention to their material environmental impact. Given the visibility of environmental issues, it is not surprising to see commercial cinema promoting eco-conscious messages, including futuristic blockbusters like *WALL-E* (Andrew Stanton, 2008) and *Avatar* (James Cameron, 2009). But the size of the carbon footprint made in the production, distribution, and consumption of these films (and their merchandising) still goes largely overlooked in media studies. The disconnect between the messages of these films and their structural conditions of production and consumption speaks volumes about the need for a more *materialist* media studies and a more literal form of “media ecology.”⁴ Media ecologists argue that media studies needs to *decenter* media, considering media forms as embedded in mediated environments rather than as isolated devices abstracted from the context and contingencies of their development and use. This is certainly advisable, and many people make this argument today. But this should also require media studies to read these environments literally. As we transition from analog to digital television and buy new laptops, mobile devices, and other media gadgets at a rapid rate, and as the cultural industries continue to consume massive amounts of energy and produce massive amounts of waste, media studies needs to address issues of environmental sustainability more directly.

The first chapter in this section begins the discussion of ecological crisis by extending the analysis beyond the media and IT industries. Charles Thorpe considers two interrelated developments: on the one hand, the destruction of the earth’s

ecosystems and species by deforestation, chemical pollution, and the effects of climate change, and on the other hand, the development of artificial forms of life in capital-intensive fields like genetic engineering, robotics, and synthetic biology. As capitalist industry devastates the existing natural world, capitalist-aligned technoscience brings into being new forms of autonomous or lifelike technologies. These twin trajectories are realizing the dystopian predictions of science fiction: a planet eviscerated of ecosystems but replete with self-generating, bioengineered life forms bred to breathe new life into the capitalist system.

In his chapter, Justin Lewis likewise underscores that the forces of capitalism are making the planet considerably less hospitable for most of its inhabitants. Lewis focuses on the role of the media and cultural industries in contributing to and promoting unsustainable models of obsolescence and hyperconsumerism. He argues that twenty-first-century consumer capitalism is failing as a model for human progress – it is no longer delivering improvements in quality of life and is fraught with economic contradictions. He focuses on three ways in which the contemporary cultural industries keep us conceptually bound to a consumerist credo. First, the media and communications industries have come to epitomize the notion of built-in obsolescence based on a perpetual consumerism. Second, our most dominant cultural industry, advertising, provides a cultural environment that makes it hard to imagine a way of being outside consumerism. Third, the capacity of journalism to question current orthodoxy is constrained by a focus on “disposable news,” displacing the more democratic function of journalism. Lewis asks how we might begin to address the failure of consumer capitalism and the complicity of the media and cultural industries, imagining a different media culture and a better, more sustainable world.

The next chapter returns to science fiction cinema as a site for visualizing and contemplating the future, in this case addressing the frightening dystopic visions of the future offered in post-apocalyptic disaster films and their metaphoric connections to the global financial crisis. Majia Holmer Nadesan examines the anxieties about global ecological devastation captured in recent cinematic disaster narratives, seeing in these films a message about the demise of liberal biopolitics. Using these cinematic themes as a springboard, Nadesan argues that financial capitalism has no interest in Western, liberal biopolitics with its focus on the welfare and productive capacities of the population. The current slate of post-apocalyptic disaster films is a cultural barometer of the malaise experienced by newly expendable populations, increasingly confronted with their excess in relation to post-disaster capitalism.⁵

In their contribution, and the final chapter of the volume, Richard Maxwell and Toby Miller continue the discussion of the global ecological crisis and its material relationship to labor, in this case bringing us back to the media industries and their workforce of below-the-line workers.⁶ The authors examine some of the circumscribed efforts of media corporations to “go green” – creating accounting practices designed to measure the ecological impact of production, while ignoring a wide range of other polluting practices and effects. Environmentally friendly accounting practices in the creative industries are confined to site-specific budgets of individual

films or studio operations, with any external environmental costs either ignored or written off as too hard to measure. As a way of envisioning a better model, Maxwell and Miller devise an imaginary world where accountants, imbued with the values of green citizenship, set off on a quest to uncover the environmental and labor conditions within the global supply chain of consumer electronics and information and communication technologies. This speculative fiction helps the authors conjure up conditions in which media producers and media studies scholars address human-centric despoliation of the Earth's ecosystems and the toxic exploitation of media workers. They propose an alternative vision of the future of media by imagining a new kind of media accountancy – and a new kind of media studies – freed from its tethers to corporate media.

Maxwell and Miller's science fiction scenario seems a fitting way to close the volume. As Donna Haraway (1991) provocatively notes in her "Cyborg Manifesto," "the boundary between science fiction and social reality is an optical illusion" (p. 149). At its best, science fiction raises critical questions about the potential uses and effects of science and technology. At the same time, the genre has a tendency toward technological spectacle, especially in its Hollywood blockbuster incarnations. Big-budget science fiction films that harness the latest technologies of cinematic illusion function much like World Fairs once did, offering up dramatic and convincing visions of an already-established future – a non-negotiable fate that has in some sense already happened. This tension at the heart of science fiction between social critique and technological spectacle, between cautionary tale and authoritative vision, provides a productive allegory for the tension between resistance and pleasure, labor and leisure, which characterizes most people's relationship with media. Whether we are lulled into complacency by the technological spectacle or rallied to the struggle for a more sustainable future depends to a significant extent on whether we believe that future has already been decided, or whether it is still open to negotiation.

As I have argued elsewhere, to build a lasting commitment to a more sustainable future, media studies needs to kick its addiction to "new media" (Gates, 2009). By this I do not mean to suggest that scholars should stop studying the Internet, videogames, or social and mobile media. Instead, we should be more diligent about interrogating the logic of "newness" that is driving the unsustainable, expansionist tech economy, rather than starting from the assumption that this or that form of media is "new" and therefore by definition more exciting to own, play with, and study. "By continuing to use terms such as old and new media without critical reflection or analysis," Lisa Parks (2007) notes, "media studies scholars risk inadvertently reinforcing the imperatives of electronics manufacturers and marketers" (p. 33). The relevancy of media studies should not be measured by how skilled the field is at predicting the future, or how fast it embraces new technologies as interesting and important objects of study. Instead, its success should be measured by how open it is to a wide world of participants, and how much it contributes to "passing around the real profit of life." After all, the field of media studies, much like most people on the planet, does not have one future but many possible futures, including no future at all.

NOTES

- 1 See also Huhtamo (1997), Huhtamo and Parikka (2011), and other work in the domain of “media archaeology.”
- 2 In Maurizio Lazzarato’s (1996) definition, “immaterial labor” refers to “the labor that produces the informational and cultural content of the commodity.” The concept points to changes in work processes that have occurred along with the rise of the digital economy, where more and more labor involves interfacing and integrating with computers. The application of the concept to social media is typically associated with a second dimension of immaterial labor: “the activity that produces the ‘cultural content’ of the commodity” (Lazzarato, 1996). These activities are not typically experienced or recognized as labor – things like “defining and fixing cultural and artistic standards, fashions, tastes, consumer norms, and more strategically, public opinion” (Lazzarato, 1996). “Immaterial labor” is not limited to the Internet, and in fact the concept helps elucidate the blurry distinction between online and offline social activities. “As a collective quality of the labor force,” writes Tiziana Terranova (2000), “immaterial labor can be understood to pervade the social body with different degrees of intensity” (p. 42). A vast pool of immaterial labor supports the major capitalist endeavors of Facebook, Google, and YouTube, as well as the lesser websites and services that populate the online world. Much like the unpaid domestic labor that women have long performed, these types of activities are typically not recognized as work precisely because there are different kinds of cultural pressures and motivations to perform them.
- 3 The statistics gathered by Internet World Stats (2010) suggest that while English is still dominant, speakers of other languages are gaining ground as a percentage of users of the Internet, especially Chinese. The actual language distribution of the websites on the Internet is impossible to measure.
- 4 On materialist approaches to studying digital media networks, see Jeremy Packer and Stephen Crofts Wiley (2012).
- 5 Nadesan’s argument about the death of biopolitics, and Thorpe’s argument about the capitalist pursuit of artificial life on a dead planet, both find support in recent work by two economists at the MIT Center for Digital Business, whose book *Race Against the Machine* examines the role of technology in the “jobless recovery” (Brynjolfsson & McAfee, 2011). Their research shows that the pace of automation in the service sector is accelerating, as technologies like robotics, computerized inventory control, and voice recognition systems take jobs that previously required uniquely human abilities. As resources continue to be directed toward improving complex automated systems, we can expect to see a precipitously declining demand for human labor in a wide variety of sectors.

Media Studies

The Interdiscipline of the Present and the Future

Angharad N. Valdivia

Media studies is a rapidly growing, widely relevant, and evolving field – an interdiscipline (Valdivia, 2003). While some scholars have bemoaned the loss of focus on process and effects, especially on milestone studies (DeFleur, 1998), others find the breadth and porous contours to be conducive to a worthwhile intellectual pursuit (Sterne, 2005). To be sure, between 1998 and the present, there has been a huge growth in interpretive and critical approaches, which have nonetheless flourished in the margins as the effects paradigm – the stuff of milestones – has firmly retained its central place in the field, at least in the United States and the Netherlands. Indeed, efforts to map out the diversity of the field of communication (Craig, 1999, 2001), which we might call the broader umbrella for media studies, yield a multiplicity of sometimes overlapping and other times mutually exclusive approaches. The terrain of contemporary media studies acknowledges that most of us live in intensely mediated environments, so that Livingstone (2009) writes on the mediation of everything, and Hay (2000) writes of refrigerator studies. The former expands on how media and communication are “ever more crucial in today’s world” (Livingstone, 2009, p. 13), and the latter asks us – as a field over a decade ago, while continuing to encourage us (Hay, 2010, 2011) – to consider the broader web of networks to which other technologies, such as refrigerators and toasters, contribute in terms of routines and practices that serve to mediate the world for us. The latter line of questioning has proven immensely prescient as many of us live in highly networked webs of media and communication, where not only can our location be pinpointed at any given moment thanks to elements in our mobile technology, but also, if we chose to, we can broadcast a narrative of our location and other audiovisual bits of information constantly to many – such as our hundreds of Facebook friends and Twitter or Tumblr followers.

Nonetheless, whether we are talking of old media technologies or institutions (see Nerone, Volume 1, *Media History and the Foundations of Media Studies*), we are witnessing the constitution of new audiences and a shift in traditional audiences (see Parameswaran, Volume 4, *Audience and Interpretation*) through the invitation offered by seductive content in a dynamically converging and synergized media environment (see Mazzarella, Volume 3, *Content and Representation*). The effects of these technologies and content continue to be measured and studied (see Scharrer, Volume 5, *Media Effects/Media Psychology*). While media platforms and patterns of production are converging, enduring tendencies toward concentration of ownership and control of media industries coexist with the emergence of new patterns of labor, practices, and updated forms of exploitation (see Mayer, Volume 2, *Media Production*, as well as some chapters in Gates, Volume 6, *Media Studies Futures*). This is not surprising given the rapidly expanding new media and communications technologies, many of whose functions replicate previous technologies while other uses (and abuses) bring new possibilities, utopian and dystopian, to the fore (see Gates, Volume 6). Unexpected global locations of nodes of influences result in previously unsuspected transnational alliances and networks (Castells, 2009).

As an early caveat to this triumphal celebration of media, I must remind readers that most of the above sentiment refers to a media-rich group that luxuriates in a wealth of networks and technologies. Yet we must not forget that even as I write this introduction at the very end of 2011, fully 50% of the global population have intermittent access to electricity. Mobile telephony may be widely spread, but the radio remains the most reliable global medium (see the *Journal of Radio Studies*). Beyond the fact that it is cheap, it neither relies on nor requires electricity or literacy, in English or any language. Furthermore, despite our current fixation with digital, wireless, and mobile media technologies, in times of crisis – whether natural such as a huge earthquake or in wartime – when the electric networks are down and we are thrown back into old school forms of media and communication, radio returns to its central location as a reliable and essential medium. So before you continue reading this introduction, or continue to read any of the absolutely outstanding volumes of this encyclopedia project, go out and buy yourself a radio – one that is both electric and battery powered. You might never need it, but if you do, you will be very relieved to have it.

The fact is that media are everywhere, and nearly everyone shares lifelong experience with and expertise on particular forms of media. Dating back to the 1920s – as identified both in Nerone, Volume 1 and Mazzarella, Volume 3, the study of media has been multi-modal and heterogeneous. Theoretical and methodological complexity has grown since the Payne Fund Studies. International, transnational, and global perspectives have become absolutely essential. Not that they ever were not, but now that media are produced, consumed, and circulated transnationally, media studies has to take this into account. Inclusivity of the heterogeneous components of the population in regard to the media has also grown. Scholarship that was once nationally bound and focused on White middle-class males has expanded to take into

consideration gender, nation, region, age, ethnicity, sexuality, ability, and class. Furthermore, as both Downing (2003) and Castells (2010) remind us, we must not forget the importance of religion in the contemporary world, as many armed conflicts revolve around religion, and media content, production, audiences, and effects are interlaced with religious impulses.

Media studies is an interdiscipline. As such it draws on and benefits from a number of contributing fields such as history, philosophy, psychology, political science, education, literature, and sociology. Yet even as it draws on those many fields, it is its own area of studies. Too often other fields, whose interdisciplinarity takes them into media studies, see this interdiscipline as new – as in, “oh look, we just discovered that we ought to look at media.” Our field becomes the direct object of other scholars’ deployment of the myth of discovery. Just like Columbus discovered “America,”¹ scholars from other fields continue to “discover” media and media studies. A century’s worth of theories and research disappears in the process, and many of us often find ourselves in other disciplines’ conferences listening to presentations that implicitly suggest direct effects, transparency, mimetic images, and so on. Transparency, when media content, industries, audiences, and practices are treated as if they spoke for themselves, as if there were no mediation, is often the tactic taken by scholars outside our discipline. What we as a field contribute to the understanding of culture and society is, at the very least, that mediation is complex and that understanding mediation helps us to uncover patterns of power, distribution, and potential justice. Media studies is about unearthing and maximizing the democratic potential of practices, institutions, technologies, and audiences that pervade our contemporary life.

Nonetheless, as Gates reminds us in her introduction to Volume 6, one central question for both the present and future of media studies concerns the very definition of media: What counts as media now that it no longer makes sense to limit the term to film, television, audio, and print? Does it still make sense to refer to a broad concept or category of “media”? If the more appropriate terms are “digital media” or “new media,” then what do *these* terms encompass? Terms like “convergence,” “remediation,” “interactivity,” and “user-generated media” capture a general sense of current transformations, but what are some productive ways of parsing out the complex dimensions and issues that these terms encompass? By paying careful attention to issues of history and context, this encyclopedia seeks to trouble the usage of these terms even as they are used rather carelessly in popular culture and public policy.

The six separate volumes of this encyclopedia were present as six separate sections in *A Companion to Media Studies* (Blackwell, 2003), the volume that provides the model for this encyclopedia and that was, in turn, modeled after McQuail’s *Mass Communication Theory*. The editors of the individual volumes put together a stellar cast of authors who in turn produced original chapters. All volume editors were asked, indeed implored, to compose a table of contents that was inclusive in many ways. First, inclusivity in terms of global topics was paramount, and we strived for inclusivity in terms of authors and global regions as well. This, as I have discussed elsewhere (Valdivia, 2011b), is not as easy as it sounds. Differential access to the latest

research, culturally different approaches to writing and developing an argument, resources that might enable a given scholar or team to develop a project and get it ready for publication, and so on, are all variables that effectively discriminate in favor of those of us in well-funded research universities in wealthy countries. We recruited some scholars whose work we translated into English, and all editors worked assiduously to cast as global a network as possible.

Another element of inclusivity was paradigm diversity. Schooled at the Institute of Communications Research (ICR) at the University of Illinois, I am the recipient of an educational tradition that highly values paradigm inclusivity. Insofar as it was possible, we included scholars using quantitative and qualitative approaches, sometimes both of them at the same time. Obviously the *Media Effects/Media Psychology* volume focused solely on the social scientific tradition, while both the *Content and Representation* and *Audience and Interpretation* volumes included scholarship using both approaches. A third element of inclusivity was gender, race, and sexuality diversity. Cutting across as a focus that can be conducted in the research included in any of the six volumes of this project is the work of transnational feminism and globalizing gender studies (Hegde, 2006). Editors sought scholarship that would include these vectors of difference, as media studies really makes no sense without their consideration. Yet even within each of these categories we encounter new gaps that merit more research. For example, as Mazzarella mentions in the introduction to Volume 3: “the reader might notice that the volume is heavy with studies of cultural representations of females. Indeed, seven chapters deal with some aspect of this topic, while only one deals with masculinity. Yet this is representative of the field, as studies of media portrayals of women and girls have been very prolific, and media studies scholars have only recently begun to seriously study mediated portrayals of masculinity(ies) (Mazzarella, 2008).” The rise of masculinity studies follows feminist studies as a logical move once we realize that femininity is socially constructed. Indeed, this is a process that this collection of volumes entices us to accomplish: a greater degree of preciseness to this complex concept of media studies, which all of us who work within the interdiscipline intellectually seek to explicate.

As a final note about process, these volumes have been peer reviewed in an innovative manner for an edited collection. First, each table of contents was submitted to the peer review of a senior scholar within that area of the field and edited accordingly. Then, as the chapters came in, within each volume authors reviewed other chapters. Ideally, each chapter was reviewed by two other authors as well as by its editors. As the overall editor of the project, I carefully reviewed all volume editor introductory chapters. Now the review process is turned over to you, the reader.

Media Studies Today

As an organizing principle for this book, I have followed since 2003 the structure provided by many different editions of Denis McQuail’s *Mass Communication Theory*:

An Introduction. Dating back to the first edition in 1983 and up to the sixth edition in 2010, whose name has changed, appropriately enough, to *McQuail's Mass Communication Theory*, Denis McQuail provided a manageable way of dividing up the field into components that, while overlapping – as they had to be since these components were teased out more for scholarly inquiry than because they are discrete and differentiated – provided a useful way to look at the breadth of study of the media. We all experience media as an integrated experience. Media inherit values and histories that are in turn explicitly or implicitly incorporated into their production; then we either consume and/or interpret media in relation to regimes of representation, with particular audiences and interpretive tactics in mind, with some desired effects over which we have little control, and contributing to a future that – like effects – we wish we could influence but really cannot. Still for the purposes of research, we tease out the media experience into a number of areas.

The volumes of this encyclopedia match the sections of the *Companion*, which used McQuail's schema and added the “futures” section. Thus we have history, production, content and representation, audience and interpretation, media effects/media psychology, and futures. We will later add a “methods” volume to complete the encyclopedia. While these areas are teased out for the purposes of research, there is great cross-pollination by scholars in media studies. We find that some scholars use both qualitative and quantitative methodologies, or at least rely on both. We also find that many scholars write about two or more of the six areas mentioned above. In fact, many of the major trends in current research encompass holistic media studies approaches. Among these contemporarily salient research projects are network analysis (e.g., Castells, 2009, 2010; Chan, 2007, 2011, forthcoming; Gilbert, Karahalios, & Sandvig, 2010); girl studies (Banet-Weiser, 2011; Durham, 2004; Projansky, 2007a, 2007b, 2010; Valdivia, 2008, 2009, 2011a); transnational feminism (Hegde, 2006; Molina Guzmán, 2010; Valdivia, 2011b); and neoliberalism as an undergirding framework of analysis (Banet-Weiser, 2011; Hay, 2000, 2010, 2011; Hoerl & Kelly, 2010; McCarthy, Pitton, Kim, & Monge, 2009). McCarthy (2011) expands the focus of neoliberalism in media to the educational system and the efforts of many cities, such as Chicago, to become a cosmopolitan, globally vibrant center of economic activity, thus linking media studies to educational policy studies.

Many of these recent research tendencies converge in the critical examination of the “posts.” Scholars develop amazing analyses demonstrating the potential of an intersectional approach that uses race, ethnicity, gender, ability, sexuality, and class all at once, for people experience these elements in an integrated manner. Roopali Mukherjee's *The Racial Order of Things* (2006) set the bar for intersectional analysis of the “post-soul” era. Tasker and Negra (2007) provide a comprehensive introduction to the political implications of postfeminist culture, while Molina Guzmán and Valdivia (2004) apply the intersectional approach to the study of celebrity Latinas. Joseph (2010), in her provocatively entitled “Tyra Banks is Fat!” (a title that, to be fair, comes straight out of tabloid magazines and television coverage), explores the implicit racism and sexism of the postracial and postfeminist veneer of reality television in general, and Tyra Banks's brand in particular. Molina Guzmán (2010) explores

the transnational deployment and commodification of the Latina body, both spectacular and everyday. The politics of the post appears in all elements of media studies as these scholars foreground media studies even as they situate their work within a broader context of geopolitics and the dynamically changing mediascapes. While it may be fashionable to suggest the end of media studies, just as others have previously declared the end of history or of ideology, what this encyclopedia convincingly illustrates is the field's ability to expand as new practices, technologies, and institutions arise. As many of the editors and contributors will document, "new media" is a misnomer as neither the technology nor the uses or assemblages are so new (see Morley, 2006). What at first may seem to be epochal breaks are revealed by many of the contributors to be far more continuous elements in relation to history, culture, and media.

Editors and Volumes

We begin with normative theories and history. **John Nerone**, author of *Violence Against the Press: Policing the Public Sphere in US History* (1994), co-author, with Kevin Barnhurst, of *The Form of News: A History* (2001), and co-author and editor of *Last Rights: Revisiting Four Theories of the Press* (1995), as well as author of many other journal articles and book chapters, is the perfect historian to lead us through this fertile terrain of scholarship. Volume 1 on history underscores that while all media have long histories, historians agree neither on the definitive tale of origin nor on the particular historical approach. Moreover, Nerone, the careful historian, alerts us to the fact that even our use of the word media in relation to communications is quite recent.

Nerone's volume includes normative and historical approaches. Historical research, drawing on normative frameworks or not, continues to offer media studies scholars great insight and tools with which to understand contemporary media. Furthermore, there is great diversity within historical approaches to media studies. Beyond cultural memory and special effects as components of media history, we are also witnessing an explosion of careful work that revisits the archive, data, and documentation. Kafka (2009) brilliantly studies that most elemental component of media – paper. It seems like such a simple task: how do we study the construction and use of paper, the "bureau" in bureaucratization, the work of scribes? Kafka concludes that: "As scholars continue to research the history of paperwork, we need to keep in mind that we are defending not only the 'historical record,' but the political one" (2009, p. 352). Indeed, these are the perfect words to keep in mind as we read the volume on history so elegantly crafted by John Nerone.

Volume 2, *Media Production*, is composed by **Vicki Mayer**. Among the many publications by Mayer, we can list *Below the Line: Producers and Production Studies in the New Television Economy* (2011), *Producing Dreams, Consuming Youth: Mexican Americans and Mass Media* (2003), and *Production Studies: Cultural Studies of Media Industries*

(co-edited with M. J. Banks and M. T. Caldwell, 2009). Mayer begins her volume by reminding us that “[M]edia production is frequently the most invisible aspect of our relationships with media. In the storm of media messages we encounter, we rarely consider where they came from, who made them, and how.” We expect to find, and we are not disappointed, a combination of keen attention paid to the sociological approach to our field, something about which McQuail had previously written in *Towards a Sociology of Mass Communications* (1969), and the more critical analysis of neo-Marxist political economy now accompanied by a focus on labor issues in the global setting. Moreover, as explicitly stated in one of her book titles, Mayer paradigmatically maintains a dialogue between political economy and cultural studies, an approach that resonates with globally used approaches in our field. The tension between structure and agency pervades this fine volume. Mayer remarks that “[I]f the focus on social structures has implicated the modern state in the study of media production, the focus on the agency that people exert over media production implicates the modern project to create enlightened subjects who can embody, perform, reflect on, and actually become media producers.” So the new production studies is global by necessity as transnational ownership and production of media industries cannot be denied; blends political economy and cultural studies; foregrounds issues of labor, both above and below the line; and takes up issues of networks, intellectual property, and subjectivity as producers are constructed in terms of categories of identity.

Sharon Mazzarella, a prolific scholar of issues of youth and the media, leads us through the wide world of “content and representation.” Author or editor of books including *Girl Wide Web 2.0: Revisiting Girls, the Internet, and the Negotiation of Identity* (2010), *20 Questions about Youth and Media* (2007), *Girl Wide Web: Girls, the Internet, and the Negotiation of Identity* (2005), and *Growing Up Girls: Popular Culture and the Construction of Identity* (2001), Mazzarella is a rigorously trained social scientist who also pursues qualitative research. As such she is the ideal editor for this volume, which is respectful of both of those methodological approaches. Indeed, for many a budding media studies scholar, content and representation provide the first point of entry, as these are the aspects of media that we experience most directly. Although, of course, all media have normative implications, histories, and a complex web of production, most people focus on the finished product: the television show, the movie, the blog, the social media website, the song, the newspaper, the advertisement, the catalogue. Content analysis is alluring yet amazingly difficult to carry out. Representational analysis also bears the sophistication of a range of theories. Neither is an easy task, and quantitative approaches complement interpretive studies. Mazzarella presents a persuasive argument as to why content/representational analysis remains an essential component of media studies and why projects that are well carried out tell us much about the world and the circuit of culture. Unsurprisingly, this area of research continues to be plentiful.

Radhika Parameswaran edits Volume 4 on audience and interpretation. Parameswaran’s research includes two long articles in *Journalism and Communication*

Monographs, “Melanin on the Margins: Advertising and the Cultural Politics of Fair/Light/White Beauty in India” (2009, co-authored with K. Cardoza) and “Global Media Events in India: Contests Over Beauty, Gender, and Nation” (2001). Her work has focused on the intersection of feminist cultural studies, gender and media globalization, South Asia, and postcolonial studies with a particular emphasis on issues of audience and interpretation. As such she constructs a volume worthy of her areas of expertise, with plenty of chapters illustrating global and gender issues. This volume also bears the traces of an interdisciplinary field that includes social scientific paradigms such as uses and gratifications as well as more humanist approaches that now include global and online ethnographies. Parameswaran remarks that “audience studies has not only survived the backlash against its populist tendencies in the late 1980s to mid-1990s, but it has also thrived and expanded to include a range of audiences, media genres, modes of audience engagement, and institutional and international sites of reception.” “Populist tendencies” refers to the “discovery” of the audience around every corner, as it were, without proper attention to issues of power and structure. In the contemporary moment, audience studies is vibrant and innovative. Whether we look at fans or online digital communities, to mention just two of the many possibilities, the construction and potential agency of the audience are major issues that continue to guide the production of media and subjectivities. Illustrative of the many philosophical quandaries undergirding the location of the audience within media studies is Jack Bratich’s chapter in Volume 6, as audience analysis is part of the present and future of the field. In addition, audience connects with issues of production as it undeniably takes labor to be part of any audience.

Erica Scharrer guides us through the fifth core component of media studies, media effects and media psychology, the dominant paradigm in the United States as well as in other global settings such as the Netherlands, and the paradigm that reaps the most funding in a positivist framework that values scientific demonstration of impact. Scharrer has co-authored, with G. Comstock, *Television: What’s On, Who’s Watching, and What it Means* (1999), *The Psychology of Media and Politics* (2005), and *Media and the American Child* (2007), and, with L. Weidman and K. Bissell, a long article in *Journalism and Communication Monographs*, “Pointing the Finger of Blame: News Media Coverage of Popular-Culture Culpability” (2003). Scharrer brings to the volume on media effects/media psychology a long-standing engagement with the social scientific paradigm in our field. A well-carried-out effects study tells us much about the influence of media on individuals, groups, and societies. The field of media effects, therefore, is presented with both the challenge and the opportunity to sort out these complex and potentially idiosyncratic experiences in a context in which the number of media outlets has proliferated, their use occurs at virtually any location and time of day, and their consumption and purposes intersect and converge more than ever before. Thus Scharrer asks: “Why are individuals drawn to media to such impressive degrees? How do they process and make meaning from media messages? What types of content are they both receiving and creating when spending time with

media? What are the consequences of such media use? What factors and conditions help explain why individuals vary in their responses to media? And what factors and conditions may moderate or mediate such responses?" These questions require complex methodological and theoretical expertise to answer. Many of us were schooled in a critique of the "hypodermic needle" model, though we have since learned that the media sometimes have or generate direct effects. Why else does a multibillion dollar advertising industry exist in the United States? However, we continue to marvel at the long-term cumulative effects that are far more complex than we originally anticipated. Furthermore, effects scholars, such as many of those contributing to Scharrer's volume, seek to explore how to effect positive change as well as how to avert more nefarious outcomes.

Finally for now,² the encyclopedia concludes with Volume 6 on media studies futures edited by **Kelly Gates**. Gates's own research is the veritable embodiment of a focus on futures. Author of *Our Biometric Future: Facial Recognition Technology and the Culture of Surveillance* (2011) as well as co-editor with Shoshana Magnet of *The New Media of Surveillance* (2009), Gates studies the discursive formation of the wishful deployment of recognition technology with an "almost gleeful futurism" that suggests "if only" the systems were in place, before 9/11, for instance, our present and future would be different, better, and so on.³ Futures is, by definition, a transient category, as within 10 years the content of this volume will be the stuff of the present, or maybe even the recent past. As Raymond Williams has written, we cannot anticipate what will be an emergent media form until it is *post facto*. The futures volume takes up some of the issues around Internet, gaming, social media, mobile telephone in a converged media form, biopolitics, and digitalization technologies such as biometric body scans. Gates asserts that media studies needs to take seriously the possibility that *radical uncertainty and contingency* are the only features that define where media are and where they are headed. All of the chapters in this volume could be retrofitted into the other five volumes. Yet together they compose a vision of the field as it moves forward, taking up issues that date back centuries, engaging them with theories and modes of media that only apparently represent new terrain.

This is the state of the art of media studies. It is a field where we know better than to use the term "new" media – for all media are somewhat new but also very old in many of their aspects. Scholars in this encyclopedia take us back to the production of paper even as they bring us up to the latest technologies, assemblages, and institutions that arise to mediate our world. Contributors to this encyclopedia share the belief not only that media studies is an academic exercise, but also that by engaging in this important area of studies we are somehow contributing to a more just vision of the world. As the separate volumes build on each other, whether we are engaged in media at any of their analytical nodes (production, content and representation, audience and interpretation, media effects/media psychology), we are simultaneously linked to its history and its future. As a diverse heterogeneous field that is global, interdisciplinary, intersectional, multi-methodological, I cannot imagine a more exciting and potentially liberatory academic enterprise to be involved with.

NOTES

- 1 In this introduction and whenever possible, this encyclopedia uses “America” to refer to a continent and “US” or “United States” to refer to the country, unless we are quoting from scholarship that uses “America” otherwise.
- 2 A *Methods* volume is projected to be released at a later date, edited by Fabienne Darling-Wolf.
- 3 Few people know that Gates submitted her dissertation proposal the day before 9/11. What to the committee seemed like futuristic queries became the very real present within a period of 24 hours.

Media Studies

The Interdiscipline of the Present and the Future

Angharad N. Valdivia

Media studies is a rapidly growing, widely relevant, and evolving field – an interdiscipline (Valdivia, 2003). The release of the final volume on *Research Methods in Media Studies* highlights the tone of this *International Encyclopedia of Media Studies*. DeFleur (1998) bemoaned the loss of focus on process and effects, especially on milestone studies, yet this methods volume of the encyclopedia illustrates that milestones and focus on processes and effects are alive and well. Sterne (2005) correctly finds the porosity and dynamism in the field to be one of its greatest strengths. Between 1998 and the present, there has been a huge growth in interpretive and critical approaches, as illustrated in all of the volumes in this encyclopedia. Nonetheless qualitative approaches have flourished in the margins as the effects paradigm – the stuff of milestones – has firmly retained its central place in the field, at least in the United States and the Netherlands. As Darling-Wolf in this latest volume of the encyclopedia, *Research Methods in Media Studies*, attests, “the formidable question of method” is an indication of the relevance, dynamism, and evolution of the field. Indeed, efforts to map out the diversity of research and methods in the field of communication (Craig, 1999, 2001), which we might call the broader umbrella for media studies, yield a multiplicity of sometimes overlapping and other times mutually exclusive approaches. Contemporary media studies acknowledges that most of us live in intensely mediated environments, so that Livingstone (2009) writes on the mediation of everything, and Hay (2000) writes of refrigerator studies. The former expands on how media and communication are “ever more crucial in today’s world” (Livingstone, 2009, p. 13), and the latter asks us – as a field over a decade ago, while continuing to encourage us (Hay, 2010, 2011) – to consider the broader web of

networks to which other technologies, such as refrigerators and toasters, contribute in terms of routines and practices that serve to mediate the world for us. The latter line of questioning has proven immensely prescient as many of us live in highly networked webs of media and communication, where not only can our location be pinpointed at any given moment thanks to elements in our mobile technology, but we can also, if we so choose, broadcast a narrative of our location and other audio-visual bits of information constantly to many – such as our hundreds of Facebook friends and Twitter or Tumblr followers.

Whether we are talking of old media technologies or institutions (see Nerone, Volume 1, *Media History and the Foundations of Media Studies*), we are witnessing the constitution of new audiences and a shift in traditional audiences (see Parameswaran, Volume 4, *Audience and Interpretation in Media Studies*, and Darling-Wolf, Volume 7, *Research Methods in Media Studies*) through the invitation offered by seductive content in a dynamically converging and synergized media environment. The effects of these technologies and content continue to be measured and studied (see Scharrer, Volume 5, *Media Effects/Media Psychology*) in many ways (see Darling-Wolf, Volume 7, *Research Methods in Media Studies*). While media platforms and patterns of production are converging, enduring tendencies toward the concentration of ownership and control of media industries coexist with the emergence of new labor practices and updated forms of exploitation (see Mayer, Volume 2, *Media Production*, as well as some chapters in Gates, Volume 6, *Media Studies Futures*). This is not surprising given the rapidly expanding new media and communications technologies, many of whose functions replicate previous technologies while other uses (and abuses) bring new possibilities, utopian and dystopian, to the fore (see Gates, Volume 6). Unexpected global locations of nodes of influences result in previously unsuspected transnational alliances and networks (Castells, 2009). Process and inquiry (see Darling-Wolf, Volume 7) evolve as an effort to take into consideration the complex interrelationality of locations, media, audiences, and effects.

As an early caveat to this triumphal celebration of media, I must remind readers that most of the above sentiment refers to a media-rich group that luxuriates in a wealth of networks and technologies. Even as I amend this introduction in late May 2013, fully 50% of the global population have intermittent access to electricity. For instance, news of Myanmar joining the global grid are accompanied by the fact that nearly nobody in that country has access to the Internet and electricity is patchy there at best. Mobile telephony may be widespread, but the radio remains the most reliable global medium (see the *Journal of Radio Studies*). Beyond the fact that radio is cheap, it neither relies on nor requires electricity or literacy, in English or any language. Furthermore, despite our current fixation with digital, wireless, and mobile media technologies, in times of crisis – whether natural such as a huge earthquake or in wartime – when the electric networks are down and we are thrown back on to old school forms of media and communication, radio returns to its central location as a reliable and essential medium. So before you continue reading this introduction or any of the seven outstanding volumes of this encyclopedia project, go out and buy

yourself a radio – one that is both electric and battery-powered. You might never need it, but if you do, you will be very relieved to have it.

Media are everywhere, and nearly everyone shares lifelong experience with and expertise on particular forms of media. Dating back to the 1920s – as identified both in Nerone, Volume 1 (*Media History and the Foundations of Media Studies*), and in Mazzarella, Volume 3 (*Content and Representation*) – the study of media has been multimodal and heterogeneous. Theoretical and methodological complexity has grown since the Payne Fund Studies (see this volume). International, transnational, and global perspectives have become absolutely essential. Not that they were ever not, but media studies scholars now document the fact that media are produced, consumed, and circulated transnationally. Media inclusivity of a heterogeneous population has also grown. Scholarship that was once nationally bound and focused on White middle-class males has expanded to take into consideration gender, nation, region, age, ethnicity, sexuality, ability, and class. Furthermore, as both Downing (2003) and Castells (2010) remind us, we must not forget the importance of religion in the contemporary world, as many armed conflicts revolve around religion, and media content, production, audiences, and effects are interlaced with religious impulses.

Media studies is an interdiscipline. It draws on and benefits from a number of contributing fields such as history, philosophy, psychology, political science, education, literature, and sociology. Yet even as it draws on those many fields, it is its own area of studies. Too often other fields, whose interdisciplinarity takes them into media studies, see this interdiscipline as new – as in, “Oh look, we just discovered that we ought to look at media.” Our field becomes the direct object of other scholars’ deployment of the myth of discovery. Just like Columbus discovered “America,”¹ scholars from other fields continue to “discover” media and media studies. A century’s worth of theories and research disappears in the process, and many of us often find ourselves in other disciplines’ conferences listening to presentations that implicitly suggest direct effects, transparency, mimetic images, and so on. Transparency, when media content, industries, audiences, and practices are treated as if they speak for themselves, as if there were no mediation, is a tactic often used by scholars outside our discipline. What we as a field contribute to the understanding of culture and society is, at the very least, that mediation is complex and that understanding mediation helps us to uncover patterns of power, distribution, and potential justice. Media studies is about unearthing and maximizing the democratic potential of practices, institutions, technologies, and audiences that pervade our contemporary life.

Nonetheless, as Gates reminds us in her introduction to Volume 6, one central question for both the present and future of media studies concerns the very definition of media: What counts as media now that it no longer makes sense to limit the term to film, television, audio, and print? Does it still make sense to refer to a broad concept or category of “media”? If the more appropriate terms are “digital media” or “new media,” then what do *these* terms encompass? Terms like “convergence,” “remediation,” “interactivity,” and “user-generated media” capture a general sense

of current transformations, but what are some productive ways of parsing out the complex dimensions and issues that these terms encompass? By paying careful attention to issues of history and context, this encyclopedia seeks to trouble the usage of these terms even as they are used rather carelessly in popular culture and public policy.

The seven separate volumes of this encyclopedia were present as six separate sections in *A Companion to Media Studies* (Blackwell, 2003), the volume that provides the model for this encyclopedia and that was, in turn, modeled after McQuail's *Mass Communication Theory*. The editors of the individual volumes put together a stellar cast of authors who produced original chapters. All volume editors were asked to compose an inclusive table of contents. First, inclusivity in terms of global topics was paramount, and we strived for inclusivity in terms of authors and global regions as well. As I have discussed elsewhere (Valdivia, 2011b), this is not as easy as it sounds. Differential access to the latest research, culturally different approaches to writing and developing an argument, resources that might enable a given scholar or team to develop a project and get it ready for publication, and so on, are all variables that effectively discriminate in favor of those of us in well-funded research universities in wealthy countries. We recruited some scholars whose work we translated into English, and all editors worked assiduously to cast as global a network as possible.

Another element of inclusivity was paradigm diversity. Schooled at the Institute of Communications Research (ICR) at the University of Illinois, I am the recipient of an educational tradition that highly values paradigmatic inclusivity. We included scholars using quantitative and qualitative approaches, sometimes both of them at the same time. Obviously the *Media Effects/Media Psychology* volume (5) focused solely on the social scientific tradition, while the *Content and Representation* (3), *Audience and Interpretation* (4), and *Research Methods* (7) volumes included scholarship using both approaches. A third element of inclusivity was gender, race, and sexuality. Cutting across – as a focus that can be conducted in the research included in any of the seven volumes of this project is the work of transnational feminism and global gender studies (Hegde, 2006). Editors sought scholarship that would include these vectors of difference, as media studies really makes no sense without their consideration. Yet even within each of these categories we encounter new gaps that merit more research. For example, as Mazzarella mentions in the introduction to Volume 3:

the reader might notice that the volume is heavy with studies of cultural representations of females. Indeed, seven chapters deal with some aspect of this topic, while only one deals with masculinity. Yet this is representative of the field, as studies of media portrayals of women and girls have been very prolific, and media studies scholars have only recently begun to seriously study mediated portrayals of masculinity(ies) (Mazzarella, 2008).

The rise of masculinity studies follows feminist studies as a logical move once we realize that femininity is socially constructed. Indeed, this is a process that this col-

lection of volumes entices us to accomplish: a greater degree of preciseness to this complex concept of media studies, which all of us who work within the interdiscipline intellectually seek to explicate.

As a final note about process, these volumes have been peer reviewed in an innovative manner for an edited collection. First, each table of contents was submitted to the peer review of a senior scholar within that area of the field and edited accordingly. Then, as the chapters came in, within each volume authors reviewed other chapters. Ideally, each chapter was reviewed by two other authors as well as by its editors. As the overall editor of the project, I carefully reviewed all volume editor introductory chapters in addition to the table of contents. Now the review process is turned over to you, the reader.

Media Studies Today

As an organizing principle for this book, since 2003 I have followed the structure provided by many different editions of Denis McQuail's *Mass Communication Theory: An Introduction*. From the first edition in 1983 up to the sixth edition in 2010, whose name changed, appropriately enough, to *McQuail's Mass Communication Theory*, Denis McQuail provided a manageable way of dividing up the field into components that, while overlapping – as they had to since these components were teased out more for scholarly inquiry than because of discrete differentiation – provided a useful way to look at the breadth of study of the media. We all experience media as an integrated experience. Media inherit values and histories that are in turn explicitly or implicitly incorporated into their production; then we either consume and/or interpret media in relation to regimes of representation, with particular audiences and interpretive tactics in mind, with some desired effects over which we have little control, and contributing to a future that – like effects – we wish we could influence but really cannot. Still, for the purposes of research, we decompose the media experience into a number of areas.

The volumes of this encyclopedia match sections of the *Companion*, which used McQuail's schema and added the "Futures" section. Thus we have history, production, content and representation, audience and interpretation, media effects/media psychology, futures, and methods. While these areas are separated for the purposes of research, there is great cross-pollination by scholars within media studies. We find that some scholars use both qualitative and quantitative methodologies, or at least rely on both. We also find that many scholars write about two or more of the six areas mentioned above. For example, a scholar such as Francombe (2010) combines the study of representation with attention to issues of labor. Durham (2004) combines analysis representation with exploration of audience and interpretation. These are two recent pieces of scholarship that illustrate overlaps.

Major trends in current research apply holistic media studies approaches. Among these contemporarily salient research projects are network analysis (e.g., Castells, 2009, 2010; Chan, 2007, 2011; Gilbert, Karahalios, & Sandvig, 2010); girl studies (Banet-Weiser, 2011; Durham, 2004; Projansky, 2007a, 2007b, 2010; Valdivia, 2008a, 2009a, 2011a); transnational feminism (Hegde, 2006; Molina-Guzmán, 2010; Valdivia, 2011b); and neoliberalism as an undergirding framework of analysis (Banet-Weiser, 2011; Hay, 2000, 2010, 2011; Hoerl & Kelly, 2010; McCarthy, Pitton, Kim, & Monge, 2009). For example, McCarthy (2011) expands the focus of neoliberalism in the media to the educational system and the efforts of many cities, such as Chicago, to become cosmopolitan, globally vibrant centers of economic activity, thus linking media studies to educational policy studies.

Many of these recent research tendencies converge in the critical examination of the “posts.” Scholars develop amazing analyses demonstrating the potential of an intersectional approach that uses race, ethnicity, gender, ability, sexuality, and class all at once, for people experience these elements in an integrated manner. Roopali Mukherjee’s *The Racial Order of Things* (2006) set the bar for intersectional analysis of the “post-soul” era. Tasker and Negra (2007) provided a comprehensive introduction to the political implications of postfeminist culture, while Molina-Guzmán and Valdivia (2004) applied the intersectional approach to the study of celebrity Latinas. Joseph (2010), in her provocatively entitled “Tyra Banks is Fat!” (a title straight out of tabloid magazines and television coverage), explores the implicit racism and sexism of the postracial and postfeminist veneer of reality television in general, and Tyra Banks’s brand in particular. Molina-Guzmán (2010) explores the transnational deployment and commodification of the spectacular and everyday Latina body. In exploring the politics of the “post,” these scholars foreground media studies even as they situate their work within a broader context of geopolitics and dynamically changing mediascapes. This encyclopedia convincingly illustrates the field’s ability to expand as new practices, technologies, and institutions arise. As many of the editors and contributors will document, “new media” is a misnomer as neither the technology nor the uses or assemblages are so new (see Morley, 2006). What may at first seem to be epochal breaks are revealed by many of the contributors to be far more continuous elements in relation to history, culture, and media.

Editors and Volumes

We begin with normative theories and history. John Nerone, author of *Violence Against the Press: Policing the Public Sphere in US History* (1995), coauthor, with Kevin Barnhurst, of *The Form of News: A History* (2002), and editor of *Last Rights: Revisiting Four Theories of the Press* (1995), as well as author of many other journal articles and book chapters, is the perfect historian to lead us through this fertile terrain of scholarship. Volume 1 underscores that while all media have long histories, historians

agree neither on the definitive tale of origin nor on the particular historical approach. Moreover, Nerone, the careful historian, reminds us that even our use of the word “media” in relation to communications is quite recent.

Nerone’s volume includes normative and historical approaches. These overlapping areas of study continue to inform the interdiscipline, and my singling out of a few representative recent pieces of scholarship below is not meant to be exhaustive, but rather illustrative of the ongoing work. For example, Christians (2010) continues his leadership in the field of media ethics as he strives to expand the framework from a Western individualist universalism toward a communitarian model that takes into account a broader number of regions and countries. Similarly, Hartley (2007) takes us to China’s *Super Voice Girl*, its version of *American Idol* that is the US version of the British *Pop Idol*, to chart the global expansion of reality television. Plebiscitary industries and the loose equation of reactive entertainment votes with civic participation in a democratic process are issues at the core of contemporary discussions, or rather popular celebrations, of the democratizing influence of market-driven free labor from constructed audiences. In particular Hartley singles out China, where the political regime continues its very hands-on approach to issues of popular discussions even as the media are becoming increasingly commercialized and adapting Western genres. Indeed, the entire deployment of reality television overlaps with discourses of neoliberalism as it shifts responsibility from the state and the collective to the moral labor of individuals (Hay, 2010, 2011; McCarthy et al., 2009; see also Bailey, 2011; Banet-Weiser, 2011), though this is an intrinsically contradictory position in places such as China where the state insists on making decisions, especially regarding media content regulation, even as it shifts moral and economic responsibility to individuals.

Historical research continues to offer media studies great insight and tools with which to understand contemporary media as well as a great diversity of approaches. Contemporarily studies of memory provide a welcome contribution to media studies. Not surprisingly, Brockus (2004) examines the location of Disney in the US collective cultural memory and national identity. Disney studies is one way of charting US media industries, content, and audiences, especially in terms of media convergence and synergy at a global level. Another topic, special effects, something nearly all Hollywood blockbusters rely on, has received nearly no historical attention from media scholars until Turnock (2009, 2010), began to develop a history of special effects dating back to the production of *Star Wars* and the Industrial Light & Magic (ILM) studio, which became the standard for special effects even to this day.

Beyond cultural memory and special effects as components of media history, we are also witnessing an explosion of work revisiting the archive, data, and documentation. For instance, Gitelman (2006) takes a fresh approach to the study of history, pointing out that even the archives are already mediated, linking them to the so-called “new” media. While there is much talk about new media, a well-versed media scholar, whose training includes a historical overview, will remember Marvin’s (1988) brilliant admonition that old media were once new, and so will our contemporary

media be tomorrow's old stuff. In addition to Gitelman, Robertson (2009) and Kafka (2009) take us back to technologies that we might not even think of as such, to address issues that are absolutely elemental in the contemporary setting of surveillance, global (im)mobility, and access to and record of any information. Robertson (2009, 2010) instructs us on the pedagogy and deployment of identity technologies, as the passport becomes a document that vouches for our national identity and indeed our very existence. Furthermore, the passport charts the evolution of border crossings, exclusive national belonging, and record keeping of national populations as central tasks of the modern nation-state. Hadlaw (2011) takes an old school look at early twentieth-century ads for AT&T telephones which literally instructed readers not only how to use the new technology, but also why speed and time had to be reconceptualized as connected to the marketplace, capital accumulation, and surplus value. This historical work transitions us into the *Production* volume (2), as telephone consumers had to be taught to prioritize elements of daily life that were previously seen as natural and noncommodifiable. Similarly, Kafka (2009) brilliantly studies that most elemental component of media – paper. It seems like such a simple task: how do we study the construction and use of paper, the “bureau” in bureaucratization, the work of scribes? Kafka concludes that: “As scholars continue to research the history of paperwork, we need to keep in mind that we are defending not only the ‘historical record,’ but the political one” (2009, p. 352). Indeed, these are the perfect words to keep in mind as we read the elegant volume on *History* crafted by John Nerone.

Volume 2, *Media Production*, is composed by Vicki Mayer. Among the many publications by Mayer, we can list *Below the Line: Producers and Production Studies in the New Television Economy* (2011), *Producing Dreams, Consuming Youth: Mexican Americans and Mass Media* (2003), and *Production Studies: Cultural Studies of Media Industries* (coedited with M. J. Banks & M. T. Caldwell, 2009). Mayer begins her volume by reminding us that “[M]edia production is frequently the most invisible aspect of our relationships with media. In the storm of media messages we encounter, we rarely consider where they came from, who made them, and how.” We expect to find, and we are not disappointed, a combination of keen attention paid to the sociological approach to our field, something about which McQuail had previously written in *Towards a Sociology of Mass Communications* (1969), and critical neo-Marxist political economy accompanied by a focus on labor issues in the global setting. Moreover, as explicitly stated in one of her book titles, Mayer paradigmatically maintains a dialogue between political economy and cultural studies, which resonates with globally used approaches in our field. The tension between structure and agency pervades this volume. Mayer remarks that

if the focus on social structures has implicated the modern state in the study of media production, the focus on the agency that people exert over media production implicates the modern project to create enlightened subjects who can embody, perform, reflect on, and actually become media producers.

So the new production studies is global by necessity as transnational ownership and production of media industries cannot be denied; blends political economy and cultural studies; foregrounds issues of labor, both above and below the line; and takes up issues of networks, intellectual property, and subjectivity as producers are constructed in terms of categories of identity.

Production is a wide-ranging area of studies. A few examples of the state of the art in production studies follow. Chan takes up the challenge laid down by Castells and many other network scholars, and pursues a couple of case studies in Peru. The first one explores software networks (Chan, 2007) and the latter investigates ceramic production and regimes of intellectual property in relation to efforts to market that traditional craft globally (Chan 2011). Intellectual property is an important component of any discussion of production and the global circulation of media or of any form of cultural products, as Boateng (2011) has demonstrated in relation to textile production in Ghana. Both Boateng and Chan have shown that unequal power between the global North and South have widespread implications in terms of how Western-originated notions of intellectual property are deployed over global regions whose own traditions do not necessarily match individualist and market-driven definitions.

Looking at a very different type of media and group of media consumers and producers, which yet resonate with many of the production issues brought out by Boateng and Chan, Banet-Weiser (2011) connects girls' YouTube video productions with neoliberal tendencies of marketing the self within heteronormative, market-driven forms of representation. The labor investment implicit in these forms of digital interventions is also discussed in some chapters of Volume 6 on futures. Additionally, the Banet-Weiser project combines production with representation research, and provides an ideal transition into discussing Volume 3 on content and representation.

Sharon Mazzarella, a prolific scholar of youth and the media, leads us through the wide world of *Content and Representation*. The author or editor of books including *Girl Wide Web 2.0: Revisiting Girls, the Internet, and the Negotiation of Identity* (2010), *20 Questions about Youth and Media* (2007), *Girl Wide Web: Girls, the Internet, and the Negotiation of Identity* (2005), and *Growing Up Girls: Popular Culture and the Construction of Identity* (2001), Mazzarella is a rigorously trained social scientist who also pursues qualitative research. As such she is the ideal editor for this volume, which is respectful of both methodological approaches. Indeed, for many a budding media studies scholar, content and representation provide the first point of entry, as these are the aspects of media that we experience most directly. Although, of course, all media have normative implications, histories, and a complex web of production, most people focus on the finished product: the television show, the movie, the blog, someone's Facebook page, the YouTube video, the song, the newspaper, the advertisement, the catalogue. Content analysis is alluring yet amazingly difficult to carry out. Representational analysis also bears the sophistication of a range of theories. Neither is an easy task, and quantitative approaches complement interpretive studies.

Mazzarella presents a persuasive argument as to why content or representational analysis remains an essential component of media studies and why projects that are well carried out tell us much about the world and the circuit of culture.

This area of research, as is to be expected, continues to be fruitful. The few research projects I mention speak to some of the pressing issues discussed in contemporary life, including ones mentioned earlier, especially girl studies, neoliberal critique, and the politics of the “post.” A major theme is the neoliberal global regime that contours the parameters for so much of what is discussed in the popular media, sometimes discursively enabling a witch hunt of anyone who dares mention that systemic issues might be at play. For instance, Bailey (2011) examines how actor Isaiah Washington, formerly of *Grey’s Anatomy*, was made to pay for his neoliberal *faux pas* when he dared to suggest that racism was at work in the public incident that constructed him as homophobic. Given the moral economy of neoliberalism, the individual has to assume responsibility for any “sin” and follow a path of therapeutic care of the self. Washington’s assertion that some of the controversy had to do with racism attempted to shift the analysis to a structural and systemic issue, a move that is not supported within neoliberalism. Thus Washington was coded as the nonrepentant, faulty neoliberal subject. Bailey’s representational analysis foregrounds the construction of masculinity *vis-à-vis* discourses of sexuality and race. Another area of studies explores the battleground over the construction of the sign of “girls.” Chesney-Lind and Irwin (2004) reflect on the moral panic construction of contemporary girlhood, constructed as either bad or mean and neither providing a progressive possibility for this demographic category. Projansky’s (2007a, 2007b, 2010) brilliant scholarship details that girls studies is neither new nor homogeneous, nor does it even refer to an age-specific category, as the term “girl” is still loosely used in a sexist culture. Chess (2010) illustrates the gendered deployment of contemporary gaming, including advertising, that positions boys and men as producers and girls as consumers, and returns us to the elements of the implicitly heteronormative family. Similarly Lindenfeld (2007) analyzes representations of food and reveals the articulation of discourses of race and ethnicity to family and nation. Given the explosion of food pornography² now available to us through cable channels, magazines, websites, and within movies (not just Hollywood film), foodways scholars draw our attention to the manner in which food continues to be a primary signifier of identity and belonging (Ceisel, 2013).

As useful transitions from content and representation research into audience and interpretation, we consider Hoerl and Kelly (2010), Francombe (2010), and Durham (2004). Exploring the normative elements of the discursive construction of the ideal neoliberal girl who is interpellated into the Wii game *We Cheer*, Francombe (2010) and Chess (2010) provide a welcome respite from the focus on boys and gaming by studying girls’ representations and audience positions in regard to this most popular type of media (see also the extensive work of Nakamura, 2009a, 2009b, 2010, and Volume 6). Similarly, Durham (2004) takes girls’ media studies globally and diasporically by studying the relation between media and sexuality in the lives of South Asian

immigrant girls. Hoerl and Kelly (2010) take up the postfeminist discourse that is part of the neoliberal regime of representation, wherein we are interpellated into a subjectivity of agency and choice when the latter is constructed *a priori*, already ruling out some of the options for which feminists have fought. In a case study of three 2007 Hollywood romantic comedies – *Juno*, *Knocked Up*, and *Waitress* – Hoerl and Kelly explore the representation of unmarried pregnancy and the resolutions that highlight the do-it-yourself “White spunky women will triumph over all obstacles” narrative that ignores issues of power, the economy, and of course race and class. The analyses of *We Cheer!*, media consumed by South Asian girls, and contemporary Hollywood film transition us from representation to audience and interpretation.

Radhika Parameswaran edits Volume 4 on audience and interpretation. Parameswaran’s research includes two *Journalism and Communication Monographs*, “Melanin on the Margins: Advertising and the Cultural Politics of Fair/Light/White Beauty in India” (2009, co-authored with K. Cardoza) and “Global Media Events in India: Contests Over Beauty, Gender, and Nation” (2001). Her work has focused on the intersection of feminist cultural studies, gender and media globalization, South Asia, and postcolonial studies with a particular emphasis on issues of audience and interpretation. She constructs a volume worthy of her areas of expertise, with many chapters illustrating global and gender issues. This volume also bears the marks of an interdisciplinary field that includes social scientific paradigms such as uses and gratifications as well as more humanist approaches that now include global and online ethnographies. Parameswaran remarks that “audience studies has not only survived the backlash against its populist tendencies in the late eighties to mid-nineties, but it has also thrived and expanded to include a range of audiences, media genres, modes of audience engagement, and institutional and international sites of reception.” “Populist tendencies” refers to the “discovery” of the audience around every corner, as it were, without proper attention to issues of power and structure. Contemporarily audience studies is vibrant and innovative. Whether we look at fans or online digital communities, to mention just two of many possibilities, the construction and potential agency of the audience are major issues that continue to guide the production of media and subjectivities. Illustrative of the many philosophical quandaries undergirding the location of the audience within media studies is Jack Bratich’s chapter in Volume 6, as audience analysis is part of the present and future of the field. In addition, audience connects with issues of production as it undeniably takes labor to be part of any audience.

Illustrating one of the many possibilities within audience studies, Buchmann, Moore, and Fisher (2010) take up the issue of Hollywood film-induced tourism. Their case study examines the Tolkien trilogy (*The Lord of the Rings* movies which were filmed in New Zealand) and the tourism to that location that the movies have generated. This is a project that can fit in both audience and effects, for how can one argue that traveling to a real faraway country – as New Zealand is from the United States – for a hefty sum of money to attempt to relive the books and the movies that feature

a fantastic story is not a very strong and immediate effect partly induced by particular forms of very persuasive media? Since tourism constitutes a growing percentage of many countries' gross domestic product (GDP), much of it induced through mass media, it is not surprising that a journal such as the *Annals of Tourism Research* includes articles that could squarely fit within a media studies journal, including this one on film-induced tourism.

Erica Scharrer guides us through the fifth volume on *Media Effects/Media Psychology*, the dominant paradigm in the United States as well as in other global settings such as the Netherlands, as well as the paradigm that reaps the most funding in a positivist framework that values scientific demonstration of impact. Scharrer has co-authored, with G. Comstock, *Television: What's On, Who's Watching, and What It Means* (1999), *The Psychology of Media and Politics* (2005), and *Media and the American Child* (2007), and, with L. Weidman and K. Bissell, a long article in *Journalism and Communication Monographs*, "Pointing the Finger of Blame: News Media Coverage of Popular-Culture Culpability" (2003). Scharrer brings to the volume a long-standing engagement with the social scientific paradigm in our field. A well carried out effects study tells us much about the influence of media on individuals, groups, and societies. The field of media effects, therefore, is presented with both the challenge and the opportunity to sort out these complex and potentially idiosyncratic experiences in a context in which the number of media outlets has proliferated, their use occurs at virtually any location and time of day, and their consumption and purposes intersect and converge more than ever before. Thus Scharrer asks:

Why are individuals drawn to media to such impressive degrees? How do they process and make meaning from media messages? What types of content are they both receiving and creating when spending time with media? What are the consequences of such media use? What factors and conditions help explain why individuals vary in their responses to media? And what factors and conditions may moderate or mediate such responses?

These questions require complex methodological and theoretical expertise to answer. Those of us schooled in a critique of the "hypodermic needle" model have since learned that media sometimes have or generate direct effects. Why else would a multibillion dollar advertising industry exist in the United States alone? However, we continue to marvel at the long-term cumulative effects that are far more complex than we originally anticipated. Furthermore, effects scholars, such as many of those contributing to Scharrer's volume, seek to explore how to effect positive change as well as how to avert more nefarious outcomes.

Volume 6 on *Media Studies Futures* is edited by Kelly Gates, whose research is the embodiment of a focus on futures. Author of *Our Biometric Future: Facial Recognition Technology and the Culture of Surveillance* (2011) as well as co-editor with Shoshana Magnet of *The New Media of Surveillance* (2009), Gates studies the discursive formation of the wishful deployment of recognition technology with an "almost gleeful

futurism” that suggests “if only” the systems were in place before 9/11, for instance, our present and future would be different, better, and so on.³ Futures is, by definition, a transient category, as within 10 years what is now the future might be the present or even the past. As Raymond Williams has written, we cannot anticipate what will be an emergent media form until it is *post facto*. The *Futures* volume takes up some of the issues around the Internet, gaming, social media, mobile telephone in a converged media form, biopolitics, and digitization technologies such as biometric body scans. Gates asserts that media studies needs to take seriously the possibility that radical uncertainty and contingency are the only features that define where media are and where they are headed. All the chapters in this volume could be retrofitted into the other six volumes. Yet together they compose a vision of the field as it moves forward, taking up issues that date back centuries, engaging them with theories and modes of media that only apparently represent new terrain.

Emblematic of the future of media studies research, in her ongoing and not just influential but paradigm shifting body of work, Nakamura reveals the fallacy behind claims that the Internet and digital gaming left behind the body and its racialized, gendered, and ability components (Nakamura, 2009a, 2009b, 2010). She takes us into the world of digital media and the many types of labor that they absorb – from our racialized player labor to the labor that it takes to produce the virtual and material gaming infrastructure. While gaming is not new, the ways that it becomes its own subfield due to the sheer magnitude of the industry, its widespread everyday deployment, and the millions of people daily engaged in its production and consumption, make it a focal point of our field. Similarly, Meddaugh (2010) highlights the relevance of new forms of delivering news to an audience that no longer watches traditional media or reads legacy media. Comedians such as John Stewart and Steven Colbert replace the prime-time news of yesterday as a source of information, and deliver their message through alternative cultural genres such as humor to get at a deeper truth than the “objective” news.

Also a new twist on an old tactic, in a hypercapitalist age, it seems almost impossible to imagine a space or time where not everything is bought and sold in the transnational marketplace. Boycotts seem so last century to our students. Buycotts (Pezzulo, 2011), on the other hand, provide consumers with a positive tactic – to buy products that confirm consumers’ demands. This strategy works within the system to secure gains such as environmental practices. Environmental and green issues come up often in Volume 6 as many of the contributors, especially Maxwell and Miller, remind us of the massive amounts of disposable hardware, not to mention the huge carbon footprint, it takes to produce the “new media” that many of us are constantly buying to replace the previous disposable model.

Jéssica Retis’s (2011) work on flows of immigrant media from Latin America via Spain and Europe to the United States complements the work on contraflows by international communications scholars highlighted by Daya Kishan Thussu (2006) in his overview of the field. For example, the work of news flows then is taken in the field of international communications as “contraflow” – the fact that the one-way

flow from the West to the rest sometimes backs up and is thrown right back at the empire.

In Volume 7 Fabienne Darling-Wolf coheres the broad area of methods in media research. Darling-Wolf has a long track record of publications about issues of gender – masculinity and femininity – in Japanese media, trans-Asian communications research, and ethics and ethnography. She embodies the global and intersectional approach we strived for in this encyclopedia, and not surprisingly presents us with a globally diverse methods volume. Research methods in media studies have long been heterogeneous, though some histories of the field sometimes forget about qualitative milestone studies dating back to the 1920s. Nowadays both quantitative and qualitative approaches are much evolved. To begin with, computer-assisted multivariate analysis reduces to seconds what once took months and years. Everett Rogers once told a media studies conference held at the University of New Mexico that, upon his defending his dissertation, a member of his committee insisted on adding one more variable to the analysis. That addition took Rogers 15 more months of eight-hour computational work days! Converged technologies allow for eye tracking (Geise, Chapter 19) to be processed through computers and to generate immediate graphing and correlations. As with all work, in any field, the ease and speed of the process have to be backgrounded by the immense human labor that theoretically constructs the research project in relation to the most useful methods. This includes attention to ethics (Healey, Chapter 2). In addition to the analysis of established methodologies such as oral histories, survey research, interviews, content analysis, and the effects of audiovisual media on children, this volume includes chapters on autoethnographies, online ethnographies, and mixed methods. It is fitting to highlight the ongoing work by Jéssica Retis as it tracks the flow of Latina/o populations and Latina/o media as they circulate around the globe in reaction to economic crises. Retis charts the flow from countries like Peru, Colombia, and Bolivia to Spain as Latin American economies tanked. Once the Spanish economy declined and the political situation veered to the right – with conservative prime minister Rajoy replacing the left-of-center Zapatero – popular sentiment attempted to deal with a global crisis that could not be contained at a national level. Latina and Latinos, some of whom gained Spanish citizenship, flowed to England in general, and London in particular, and more plan yet another transatlantic crossing to the United States where they will enter as European or Spanish immigrants. They bring with them their media businesses and practices. The contraflow that was originally discussed in terms of media is now embodied by globally roaming populations, who take their media and culture with them and continue the millennial hybridization of both.

This is the state of the art of media studies. It is a field where we know better than to use the term “new” media – for all media are somewhat new but also very old in many of their aspects. It is a field where mixed methods and evolving methodologies attempt to capture the mediated experience and process of ever changing and reconstructed populations and audiences. Scholars in this encyclopedia take us back to the production of paper even as they bring us up to the latest technologies, assemblages,

and institutions that arise to mediate our world. Contributors to this encyclopedia share the belief not only that media studies is an academic exercise, but also that by engaging in this important area of studies we are somehow contributing to a more just vision of the world. As the separate volumes build on each other, whether we are engaged in media at any of their analytical nodes (production, content and representation, audience and interpretation, media effects/media psychology, methods), we are simultaneously linked by its history and its future. It is a diverse heterogeneous field that is global, interdisciplinary, intersectional, multimethodological, and I cannot imagine a more exciting and potentially liberatory academic enterprise in which to be involved.

NOTES

- 1 In this introduction and whenever possible, this encyclopedia uses “America” to refer to a continent and “US” or “United States” to refer to the country, unless we are quoting from scholarship that uses “America” otherwise.
- 2 Food pornography refers to the deployment of codes of pornography – such as repetition, extreme closeups, and lingering camera shots – in the coverage of food and food preparation in so much of today’s multichannel media.
- 3 Few people know that Gates defended her dissertation proposal the day before 9/11. What to the committee seemed like futuristic queries became the very real present within a period of 24 hours.

Convergence, Globalization, Technological Development, and Interdisciplinarity in a Fast-Evolving World

The Formidable Question of Method

Fabienne Darling-Wolf

ABSTRACT

This introduction makes the case for the continuing need to pay close attention to methodological issues in media studies. Locating the field within a fast-evolving global context, it outlines some of the questions of methodology media scholars must contend with, particularly as they relate to processes of convergence, globalization, and technological development. It argues that just as media are converging, media studies scholars must transcend methodological boundaries in order to continue to develop the kind of fluid interdisciplinary approaches that are best suited to explore the multimodal and heterogeneous nature of contemporary media. It concludes that, collectively, the essays included in this volume illustrate the innovative and dynamic nature of research methods in media studies and demonstrate their authors' commitment to critical and carefully contextualized work attuned to changing dynamics as well as to the researcher's own position and bearing on the process of inquiry.

The fast pace of technological development in the past few decades has rendered the task of media studies scholars particularly complex. The spread of print and electronic media, cable and satellite technology, and most recently the development of the Internet, “social media,”¹ and other forms of digital communication which facilitate the convergence of previously separate media forms have profoundly reshaped and continue to influence the way in which media are produced and negotiated in individuals’ daily lives. These developments are generating both opportunities and challenges for researchers intent on exploring the role of media in society, whether they are concerned with processes of production and distribution, with narrative content, or with audience interpretation.

Volumes 1 through 6 of the *International Encyclopedia of Media Studies* have discussed these challenges and reflected upon the evolution of the field from multiple perspectives, focusing respectively on media history, media production, content and representation, audience and interpretation, media effects/psychology, and media studies’ futures. The shifting nature of contemporary media contexts, and its potential implications for media studies, are a running theme throughout the project, leading Kelly Gates (2013) to conclude in her introduction to Volume 6 that “*radical uncertainty and contingency* are the only features that define where media studies are headed” (p. 2; see also Nerone, 2013, p. 14). Taken as a whole, the encyclopedia also illustrates, however, media studies scholars’ continuing commitment “to embrace and respect a range of methodological and theoretical perspectives . . . to remain open to evolving and refining our research questions, and to consider that perhaps we need to ask new questions as the technology and content evolve” (Mazzarella, 2013, p. 15).

Situating its discussions of the methodologies employed in media studies within this transformative moment, *Research Methods in Media Studies*, the seventh and concluding volume of the *International Encyclopedia of Media Studies*, showcases the work of scholars who critically reflect on these questions’ impact on the process of inquiry. Recognizing that “new” developments must be considered in relation to their historical antecedents and to enduring dynamics (Gates, 2013; Livingstone, 2004; Sterne, 2007), it makes the case that a critical focus on methods, whether long established or emerging, remains a central and necessary component of international media studies.

Discussions of methodology are certainly present in the encyclopedia’s other volumes. The range of methods authors employ in each book to explore various dimensions of the media – historical methods, interviews, participant observation, ethnography, surveys, text-based approaches, as well as emerging methods developed to address new media forms – have started to illustrate the diversity of approaches with which media studies scholars routinely engage. They attest to the expanding and multidisciplinary nature of the field – and I agree with Nordenstreng that it “remains rather a field than a discipline” (2004, p. 6). None of the volumes, however, has focused solely on research methods *per se* – from the nuts and bolts of developing a study to the questions of whether “old” tools can apply to new contexts and, if

not, of how to develop new ones. A volume entirely focused on these issues is, thus, a logical final step.

Taken together, the chapters collated here sketch a thorough, analytical, and historically contextualized account of the evolving and innovative nature of media studies methodologies. They revisit long established practices and illustrate their continuing productive potential, tackle ethical questions, reflect on past and current challenges, and offer new directions of inquiry. The volume outlines the productive potential that lies, from a methodological point of view, in media studies' long history of interdisciplinary engagement across social disciplines. Indeed, in a time when the ability to adapt quickly to changing conditions becomes a necessary condition to remaining relevant, the historical and current theoretical and methodological diversity of media studies research arises as a definite advantage – an advantage that I hope this volume will encourage scholars to further exploit in the future.

Just as the media are converging in terms of ownership, technologies, and audiences, media studies research has, for some time now, been moving toward a “steady convergence of theoretical orientations and methodological approaches” as “[p]ositivists have recognized the necessity to adopt methodologies that are more effective at representing and measuring audiences' involvement with and interpretations of media content,” while “critical and interpretivist researchers have acknowledged that in order properly to understand audiences, it is necessary, at least some of the time, to obtain data directly from them” (Gunter, 2000, p. 22). The volume is thus intentionally *not* divided along quantitative and qualitative lines of inquiry. As media and methodologies converge, this binary is not proving particularly useful (if it ever was). In Chapter 1 of this volume Slavko Splichal and Peter Dahlgren remind us that “The decisions as to whether it is appropriate to choose qualitative and/or quantitative methods should be based on the respective probabilities of obtaining the evidence being sought, and no method can be *a priori* excluded as inappropriate, whether quantitative or qualitative.” The essays included here powerfully illustrate the increasing and often necessary blurring of the quantitative and qualitative dimensions of research. They collectively make a case for the productive potential of shedding these methodological straitjackets in order to find more supple ways to explore the multimodal, fluid, and heterogeneous nature of contemporary media contexts.

Finally, they point to the continuing and perhaps increasingly essential need to link method to theory. All authors, regardless of their methodological orientation, aptly recognize that the two are inextricably intertwined. Their vigorous engagement with epistemological questions and power dynamics both in media practice and in the process of conducting research is a distinctive feature and key contribution of the book. Arguing that “new modes of digital communication . . . challenge the belief that it is possible to clearly separate methodology from theory,” Splichal and Dahlgren set up the tone for the rest of the volume when they conclude that these developments “make critical reflection and development in regard to theory all the more imperative.”

Situating Research Methods in Media Studies

A complete discussion of the multidimensional repercussions of the developments mentioned above on all areas of media studies research is beyond the scope of this brief introduction, and a more detailed exploration of the historical evolution of the field (and of the impact of this evolution on research methods) is provided in Chapter 1 of this volume. A few points, however, are worth noting here for their particularly thorny practical implications for the process of developing and applying research methods in media studies.

First, the multiple levels of convergence that define our media landscape are raising, as Gates puts it, “formidable questions of methodology” (2013, p. 10). Noting that the very definition of “media” becomes problematic when “media are so many different things” (p. 7), Gates concludes that “[t]he sheer quantity of media available seems to overwhelm the possibility of conducting effective studies that can be generalized beyond very limited contexts” (p. 10). Indeed, how and where are we to analyze the role of media in individuals’ lives when “people with adequate connectivity have access to a dizzying array of media forms and content” (p. 10)? How do we sort out individuals’ “complex and potentially idiosyncratic experiences” in a context in which media use “occurs at virtually any location and time of day” (Scharrer, 2013, p. 3)? Equally importantly, when operating from an environment in which “adequate connectivity” is mostly taken for granted, how do we find ways to include the 50% of the global population that does not “[luxuriate] in a wealth of networks and technology” (Valdivia in her Introduction to this volume)? How do we define a text when media forms are simultaneously distributed on multiple platforms? Which platforms do we analyze and at what point in time? What do we do about the ephemeral nature of digital environments? How do we study mobile audiences whose localities constantly shift? Can we conduct ethnography in virtual spaces, when traditional ethnography values personal and material presence and engagement? How do we define and examine media production in an era of user-generated content? How can we critically explore processes of convergence at the highest levels of ownership while keeping individual agency in mind?

Second, media scholars must contend with processes of globalization linked to the interrelated developments of new forms of global capitalism and electronic media in the second half of the twentieth century² and more recently accelerated by the rise of digital communication. The time–space compression or distancing (Castells, 1991, 2003; Giddens, 1991; Harvey, 1989) that results from the availability of instant global communication has, again, practical implications in terms of research methodologies. Once released into the complex network of informational flows that constitute our globalized media environment (Castells, 2004), media products and their reception become increasingly disconnected from their original site of production. Effectively accounting for this “deterritorialization” and “reterritorializa-

tion” of cultural forms (Appadurai, 1996; García Canclini, 1995; Tomlinson, 1999) poses a number of challenges for media studies scholars.

How do we access audiences that are more and more geographically and culturally spread? How do we study media production that takes place in complex and decentralized transnational networks? How do we make sense of the “complicated and connected repertoire of print, celluloid, electronic screens and billboards” through which audiences “construct imagined worlds that are chimerical, aesthetic, even fantastic objects” (Appadurai, 1996, p. 35)? How do we study the local in relationship to global processes that fundamentally transform “the *places* we inhabit and our cultural practices, experiences, and identities” (Tomlinson, 1999, p. 106)?

This volume will demonstrate that, in order to answer these questions sensitively, researchers – regardless of what they are studying and where they are geographically located – must develop a more sophisticated understanding of processes of transnational and/or transcultural influence and broaden the scope of their inquiries. We have to realize that we cannot simply assume that a method for studying audiences in the United States, the United Kingdom, or Canada will be useful in a transcultural context. We must understand that in the twenty-first century we are *all* “global media scholars” – not just those of us whose studies happen to focus on “foreign” locales. We must, finally, pay particular attention to the potential impact of our own experience of locality on the research we produce.

Third, the rise of digital technologies raises new practical and ethical questions for media scholars to wrestle with. If new modes of data collection and aggregation offer countless unexplored opportunities, they also create new problems. As Splichal and Dahlgren note, “Before the advent of computer-mediated communication, the ‘data at hand’ were always generated independently of communication processes under study . . . In digital communication, however, the data sets existing prior to our study consist of ‘footprints’ of personal information participants leave online while communicating.” How we choose to use this “surplus information” generated by individuals’ online activity requires careful ethical and methodological consideration. How do we judge the quality of data we did not collect ourselves? Is it ethical to use data collected without media users’ knowledge? How might the “unprecedented abundance of self-generated data” (Splichal and Dahlgren) affect what, where, and who gets studied and, perhaps more importantly, what, where, and who does *not* get studied? How do we handle privacy issues in virtual contexts that may be public from a legal point of view but perceived as private by users? How do we even know to whom we are talking?

Finally, and in addition to the constant transformation of our contemporary media-rich environment, media studies scholars have had to contend with an equally fundamental shift in the *theoretical* context(s) informing media and communication inquiry. The growing influence of poststructuralist and postmodernist critiques in the latter half of the twentieth century introduced important new questions regarding the nature of reality and the politics of representation for media scholars to ponder. The recognition that all texts are, at least to some extent, polysemic (Hall,

1997), required media scholars to develop more nuanced interpretations and approaches to media research. The parallel “crisis of representation” in anthropology raised questions as to whether studying the Other – which, in the case of media scholars, typically took the form of considering various dimensions of previously ignored media audiences or producers – was desirable, or so inextricably caught in power relations that it should be abandoned altogether (Clifford, 1986; Marcus, 1998; Wolf, 1992). This intellectual history as it informs methods will be discussed in greater detail in several of the chapters included in this volume.

Suffice it to say here that while these theoretical reflections may have had a more direct impact on some methodologies (e.g., ethnography) than others, few (if any) areas of media studies were left completely unaffected by this “ferment in the field” (Nordenstreng, 2004). From a methodological point of view, the expansion and diversification of the field of media studies – which, according to Nordenstreng has, in the past 50 years or so, “expanded perhaps more than any other academic field apart from computer science and biomedicine” (2004, p. 8) – has resulted in a continuing breakdown of disciplinary and methodological boundaries. While the study of media was always, at least to some extent, interdisciplinary in nature, it is becoming increasingly clear that the media-rich environment in which we live today is just too complex for one paradigm or one method to completely and definitively explore “all of it.”

Thus, as the varied chapters included in this volume collectively tackle many of the questions – both practical and ethical – outlined above, they also remain deeply attentive to the need to carefully contextualize our analyses. They demonstrate a keen awareness of the fact that, regardless of the method employed, researchers are typically able to provide but one piece of a larger methodological and theoretical puzzle.

As noted, “old” distinctions between methods have been fading for some time. Email interviews may have as much in common with surveys as they do with their face-to-face counterparts. A textual analysis of an ongoing blog takes on some of the dynamics of participant observation. A study of the process of sharing YouTube videos might combine elements of visual analysis, research on production, and digital ethnography. These challenges, of course, also open up some interesting opportunities. The online fan response to a television show may, for instance, prove useful in contextualizing a discourse or content analysis of the program.

Thus, just as journalists and media producers can no longer afford to work in only one medium, media studies researchers must become familiar with an increasingly wide array of methods if they are to effectively negotiate our constantly transforming media and scholarly environments. As Elisenda Ardevol and Edgar Gomez-Cruz note in their chapter on digital ethnography, “As image, sound, and movement are becoming more and more common features of social interaction . . . the digital ethnographer has to move between different research contexts and methods. With this development, the division between online and offline ethnog-

raphies tends to collapse even more and digital ethnography must be conveyed as a mediated practice, *as a remix of methods that has to be engaged with the researcher's experience*" (emphasis added). While their comment here focuses on ethnographic work, it accurately describes a process that takes place with other methods as well.

Finally, the evolving character of (multi)media environments means that we may simply have to invent new ways to explore and study the media. As Gates notes, "As a set of social and technological processes, the proliferation of networked digital media is related in complicated ways to changes in forms of social organization, communication, human identity, and subjectivity, and *media studies needs to find ways of making sense of how this is happening and what it means*" (2013, p. 8, emphasis added). Several of the chapters in this volume move in that direction by offering possible new additions to the media scholar's tool kit. These range from musical analysis (Amparo Porta) to eye tracking (Stephanie Geise) or photovoice (David Novak and Tonny Krijnen) techniques. Others propose to combine "older" methods with newer ones as a means to better explore the evolving dynamics that characterize individuals' engagement with media texts and contexts. Such efforts are illustrated, for instance, in Carolyn Michelle and Charles Davis's chapter on Q methodology or in Lillian Spina-Caza's work on perceptions of the creative self in virtual and physical activity.

Running Themes and Volume Organization

The variety of methodological approaches and theoretical inspirations represented in the chapters included in this volume powerfully illustrates the diverse and expanding nature of the field of media studies. A number of important recurring themes, however, run throughout the volume across the diversity of theoretical orientations and methodological tools discussed.

First of all, the chapters demonstrate a steady concern with ethical issues and power relations in academic work. As might be expected in this kind of volume, these concerns are the ostensible main topic of some of the chapters. The two introductory essays – Slavko Splichal and Peter Dahlgren's chapter on the historical evolution of research paradigms in media studies and Kevin Healey's reflection on the ethics of media studies research – address these questions most directly. What is unique, however, about this volume is that issues of power and ethics are discussed throughout the book.

Taken as a whole, the chapters persuasively illustrate the need to interrogate power relations both in the social environment in which media are produced, distributed, and consumed and in the process of conducting academic research. They share a commitment to identifying media studies' "blind spots," particularly as they

relate to the experiences and voices of groups and populations that have historically suffered from marginalization and invisibility in academic work and society at large – in her essay on autoethnography, Johanna Uotinen speaks of the small agency that is hidden from view in spaces that are considered “private” yet are infused with power relations. Thus, concerns over issues of gender, race, class, and/or ethnicity run throughout the book, raised by authors discussing methodologies as diverse as (oral) history (Mike Conway, Richard Popp, Mark Hampton), textual analysis (Sara McKinnon, Elfriede Fürsich), field experiments (Lillian Spina-Caza), interviews (Lorena Frankenberg and José Carlos Lozano, Sue Robinson), or ethnography (Tanja Bosch).

Collectively, the chapters recognize that discourse is never innocent, or, as Elfriede Fürsich puts it, that “meaning is created in all forms of popular culture and there is no banal entertainment that people only use to escape the mundane.” This, of course, applies to academic discourse as well. Thus, the chapters also provide ample reflection on “the epistemological relationship between the researcher and the materials” (Fürsich) to be studied, and the power relationships inherent in all forms of research whenever human beings are involved, regardless of the chosen method of inquiry – as Sue Robinson notes in her essay on interviewing, “the understanding of those power dynamics must be incorporated into the context of the answers, but also into the very approach of the interview and the protocol.” This recognition of the power of discourse further translates into a keen awareness of the need to carefully locate research within the specific historical, cultural, and social context from which it is conducted. The need to keep in mind, as Kevin Healey puts it, that “the theoretical and philosophical frameworks that inform one’s work should not be taken for granted as settled matters but as contested sites requiring self-reflection and continued engagement with a diverse community of scholars.”

From a practical point of view, the transformation of our media landscape produces some interesting challenges for the editor of a volume on research methods. The wide variety of methods being constantly developed to explore ever changing dynamics, many of which we are just beginning to understand, means that some choices had to be made and that some things were necessarily excluded. A number of scholars have warned against the tendency to dismiss “old” theories, methods, and insights in the face of rapid technological change as if new technologies did not share a historical link with earlier media forms and automatically rendered previous insights or methodologies obsolete (see, for example, Livingstone, 2004; Morley, 2006; Sterne, 2007). Keeping this warning in mind, some of the chapters in this volume focus on the methods most “traditionally” associated with media studies – surveys, experiments, interviews, content/textual analysis. The hope is that these essays will serve as a good starting point to researchers new to the method and as a useful “refresher” to more advanced scholars. The goal is also to make a convincing case for these methods’ continuing usefulness.

In the previous volume of this encyclopedia, Gates raised the question of “How useful are the concepts, theories, and methodologies developed in the days before

the rise of the Internet and digital media for understanding the new media landscape? (2013, p. 8). This volume will demonstrate that while some methods may require adaptation and while new tools may be needed to address some dimensions of our contemporary media environment, there is danger in throwing out the proverbial baby with the bath water. I strongly agree with Gates that rather than uncritically “celebrating recent innovations as radically different and inherently better” we must strive “to recognize the deeply embedded ways that the past is still with us in the present” (p. 7). The chapters in this book all demonstrate a commitment to doing so.

The volume does, however, spend much time reflecting on how research methods in media studies are evolving in order to “accommodate the challenges of this new research environment without compromising academic rigour” (Arnason, 2011, p. 98). Bringing together established scholars of national and international reputation and emerging researchers, many of the chapters in this book provide examples of how “old” methods must (and can) be adapted to better capture the complexity of new forms of communication and media production, distribution, and/or reception. They also provide exhaustive, and often brazenly honest, reflections on the challenges researchers might encounter along the way. Other essays demonstrate how our contemporary media context can be approached in new and innovative ways through research methods that simply were not available or practical in earlier times. This means that some of the methodologies discussed here are still in the early exploratory stages and may need further development, and perhaps modification, in the future.

The collation of scholars and/or research foci from different parts of the world – Argentina, Britain, Canada, Colombia, Costa Rica, Ecuador, Finland, Germany, Hong Kong, India, Mexico, the Netherlands, Norway, New Zealand, Slovenia, Spain, South Africa, Sweden (without counting my own identity as a French citizen/Japan specialist) – is another distinguishing feature of the volume, despite the remaining limitations imposed by the use of the English language for its text and by the politics of academic publishing which tend to privilege individuals with some connection to powerful “Western” institutions (myself included). While such diversity might be naturally expected of a volume included in the *International Encyclopedia of Media Studies*, few of the currently available texts focusing on research methods in media and/or communication reach far beyond the limited and familiar confines of US and British academic institutions – except, perhaps, in a separate section ostensibly focused on the study of “global” media. This volume’s relative geographic diversity – even if admittedly incomplete – thus constitutes an important contribution to the discussion of research methods as it broadens the scope of inquiry by providing insights into transcultural dynamics as well as the process of scholarly production in other parts of the world.

In an effort to provide both more general conceptual information about research methods and more specific examples of their application, this book consists of a mix of “how to” essays and specific case studies that draw from research projects

employing a variety of methods. The case studies propose to take the reader “behind the curtain” of the research to point to the decisions made along the way, to the challenges encountered in the research process, and to allow for a more contextualized reflection on the results. These case studies, thus, are not necessarily provided as “perfect” examples of how to do research – in fact, several authors discuss aspects of the research that have “gone wrong” as examples of what not to do and I believe all would agree that very few research projects ever turn out exactly as expected. They are, rather, offered as useful food for thought for scholars in the process of developing their own research projects.

This book is divided into four sections loosely organized around the themes of theoretical and ethical considerations in media studies research, conducting research with people, conducting research with texts, and the challenges of virtual environments and mixed method research. That some of the chapters could have been included in more than one section of the volume illustrates the extent to which the boundaries between different types of methods and modes of inquiry are being challenged and eroded in our current historical moment. Furthermore, as noted above, as the concept of “a text” is constantly evolving, most research projects could, in some respects, be argued to fit into Part 2. The divisions are thus admittedly artificial and intended to reflect the broader lines underlying each group of methodologies rather than to erect impervious boundaries. We construct categories in order to facilitate the process of analysis. Yet we are cognizant that we are assigning order and structure to a field that is both holistic and interconnected.

Part 1: Setting Up the Stage

“Setting Up the Stage” provides the historical and theoretical context necessary to a thorough engagement with the nature of research methods in media studies, their evolution over time and in different environments, and their ethical implications. Slavko Splichal and Peter Dahlgren begin the conversation with a historically contextualized examination of the terrain of media and communication research and its prevailing paradigms. Characterizing the intellectual history of the field of media studies as “somewhat ambiguous,” they sketch an outline of the evolution of its “loose organizing logics.” In conclusion, the authors make a case for a “reconstituted matrix of research” organized around four types of knowledge – professional, administrative, policy, and critical – as a way to think about the field of media studies that both identifies and legitimizes more varied forms of knowledge production. Kevin Healey follows with a critical examination of the underlying values and ideologies that guide media research projects and the institutional bureaucracies that govern them. Highlighting, in particular, how basic ethical concepts are complicated by the emergence of new media technologies, he also provides a more pragmatic examina-

tion of the ethical challenges that frequently arise in media studies research and some guidance on how scholars might prepare to face them.

Part 2: Working with People

“Working with People” focuses on the process of conducting research with people using a variety of methods. The section begins with discussions of methods that broadly involve asking individuals to answer questions. Suman Mishra starts with an overview of survey methodology, its historical background, and its uses in communication and media studies. In addition to reminding readers of the basics of sampling procedures, questionnaire design, questionnaire distribution, and data analysis, the chapter addresses the challenges of conducting survey research transnationally as well as discussing ethical issues specific to the method. Carolyn Michelle and Charles Davis then bridge the gap between surveys and more qualitative means of studying audiences by introducing readers to Q methodology, a methodological hybrid drawing from the strengths of both qualitative and quantitative traditions as a tool to explore individuals’ engagement with a wide variety of media texts. They take readers behind the scenes of a study using the method to explore cross-national responses to James Cameron’s 2009 feature film *Avatar*.

The next three chapters focus on the method of interviewing in its multiple forms. Sue Robinson sets up the stage here with an overview of interviewing as a process of qualitative inquiry, pointing in particular to the need to develop a critical awareness of the power relations inherent in the method. Mike Conway focuses more closely on challenges specific to oral history interviews as a method that demands “a personal interaction with the subject, and a realization that the interview is a collaborative process involving both the interviewer and interviewee.” Lorena Frankenberg and José Carlos Lozano illustrate the difficulties and rewards of both interviewing as a technique and oral history as a practice in their chapter on memories of moviegoing in Monterrey, Mexico. Describing interviewing informants about their past as a process of meaning negotiation, they point to the “rich and dense insight on the lasting meanings and values attached to participants’ media consumption habits” the method can provide. The authors also note the importance of resisting the temptation to construct nostalgic accounts of individuals’ past and the need to pay close attention to the ways in which class dynamics shape media consumers’ experiences.

Building on these insights about interviewing and its challenges, the next two chapters more broadly address (auto)ethnographic methods. Drawing on an ethnographic study of a local radio station in South Africa, Tanja Bosch critically examines the process of studying media production as an “insider” attempting to conduct theoretically informed reflexive research in her own “backyard.” She

considers how her identity as a black female manager in the station affected her relationship with informants and, ultimately, the outcome of her research. Her chapter illustrates the complexity of negotiating multiple identities in a context in which feelings of betrayal and loss of control often abound. In her autoethnographic study of the introduction of digital television in Finland, Johanna Uotinen illustrates how the method can be employed to address some of the tensions arising in the informant–researcher relationship as described by Bosch and more generally generated by the “crisis of representation” in ethnography. She proposes the concept of “small agency” as a means to examine practices connected to media that are often so routinized and privatized that they have become invisible. She strongly contends, however, that in order to be effective as a research method, autoethnography cannot “merely describe the private” but must also seek to produce “connections to the general, social, and cultural.”

The final two chapters in this section discuss experimental approaches to research. Glenn Leshner lays out the basics of what he deems a relatively underused method in media studies, particularly when compared to content analysis or surveys. In addition to describing the particulars of conducting controlled experiments, the chapter addresses some common misconceptions and controversies surrounding the method. It also emphasizes the need to link the research process to a clear theoretical framework. The section closes with a closer examination of one type of experimental design: between-subjects experiments. Here, Kim Bissell uses two case studies – an examination of anti-fat bias in grade school children and a similar study involving adults – to illustrate the strengths and weaknesses of the method. Bissell concludes that experimental design, as the primary tool for studying and understanding causal relationships, remains one of the most important methods in empirical research in mass communication and media studies today.

Part 3: Working with Texts

While most media studies research could arguably be viewed as dealing with texts at least in some respects – interview transcripts, for instance, are texts that the researcher analyses – “Working with Texts” considers methods in which a wide variety of broadly defined texts are the central element of analysis. First, Rico Neumann and Kevin Coe make a case for the utility of a mixed approach to content analysis blending computer-assisted content analysis with manual coding techniques to analyze quantitative trends in large amounts of text. They illustrate how the method was applied in an examination of apologetic rhetoric in modern presidential speeches. Along the way, they address issues of sampling – of identifying key terms and their linguistic derivatives for computer-assisted searching – and consider challenges in data collection and analysis. Matthew Lombard follows with a discussion of the “lessons learned from a research saga” involving a large-scale quantitative

content analysis of the structural features of television conducted in the mid-1990s – a project so ambitious that by the time it was ready for publication, the data were deemed obsolete by reviewers. The chapter also reflects on the original project's unexpected afterlife and on the joys and rewards of conducting research despite the challenges and frequent disappointments.

Approaching texts from a more qualitative perspective, Sara McKinnon outlines the different approaches deployed by researchers working with texts and offers a step-by-step overview of the process of conducting text-based qualitative research. She emphasizes, in particular, the need to carefully contextualize texts within the broader social, political, and cultural contexts in which they circulate and the importance of researcher reflexivity in qualitative work. Employing a critical textual analysis of newspaper food reviews of ethnic restaurants as an example, Elfriede Fürsich further explores the theoretical underpinnings of the method and illustrates how it can be used to explore the ideological dimensions of cultural discourse constructed beyond the manifest content of the text.

The increasingly prominent position of text-based historical methods in media studies is explored in the next two chapters. In his broad introductory essay, Richard Popp traces the evolution of historical methods in media studies in the wake of the cultural turn that reshaped academic study in the closing decades of the twentieth century. Locating the work of media historians in relationship to historiographic debates in the fields of history, American studies, and historical sociology, the chapter considers the primary ways in which culture has been defined and treated as an area of historical inquiry in the past few decades. It closes with an examination of three historiographic approaches that may be particularly useful to media scholars – the culture industry revisited, the history of the senses, and the history of the book. Mark Hampton then complements Popp's more theoretical approach with a detailed discussion of a range of inquiries and approaches in media history, and of the types of empirical sources media historians have at their disposition to investigate these questions.

This section closes with three chapters focused on the study of visual texts. James Walters first provides an inquiry into film analysis through a series of key texts widely used in introductory classes on the method, which he describes and carefully evaluates. Noting that "the pursuit of one defining methodology seems futile," he advocates a continuing engagement with multiple approaches, keeping in mind both the merits and limitations of each position. Stephanie Geise discusses the productive potential of combining eye-tracking technology that allows for the empirical study of processes of visual perception and information processing with other empirical methods in media studies research, where the technique is still in an emerging state. She offers her own study of shock-inducing advertisements as an example of how the method can be applied to the study of visual texts. Finally, David Novak and Tonny Krijnen's chapter on the use of photovoice – a qualitative methodology in which participants use photographs in tandem with in-depth interviews – outlines the benefits of "studying visual media with visual methods" and provides an

additional tool for media study scholars, particularly in their analyses of visual media reception.

Part 4: Virtual Challenges, Interdisciplinary Research, and Mixed Method Research

The five chapters in “Virtual Challenges, Interdisciplinary Research, and Mixed Method Research” are more loosely connected along the themes of studying virtual worlds, interdisciplinary and multimethod research. While many draw from the methods discussed so far in the book, they deserve a separate treatment in that they engage more directly with and reflect upon the changing nature of media texts and contexts – in particular the changes occasioned by the development of digital and global media – and/or provide powerful examples of how these methods can be productively combined. In other words, they collectively answer the call to address the challenges specific to virtual environments more assertively and to develop new interdisciplinary methodologies and theoretical approaches that harness the potential of virtual worlds as research venues more effectively (Arnason, 2011, p. 108).

While drawing from very different methodological and theoretical contexts, Helle Sjøvaag and Eirik Stavelin’s chapter on online news analysis and Elisenda Ardevol and Edgar Gomez-Cruz’s reflection on digital ethnography and media practice both wrestle with the dynamics of conducting research in ephemeral virtual environments. Sjøvaag and Stavelin suggest that methods of content analysis must be redesigned to account for the medium-specific features of Internet distribution. They propose a new approach to analyzing online news based on a combination of human and computer coding and on the triangulation of qualitative and quantitative measures. The authors illustrate how this approach might work through a discussion of a content analysis of online news output collected from the Norwegian Broadcasting Corporation (NRK). They also discuss the difficulties they encountered in their efforts to develop an approach that more effectively accounted for the ever-changing nature of digital information. Ardevol and Gomez-Cruz reflect on the opportunities and challenges created by the rise of virtual environments for the practice of ethnography. They note, in particular, how the increased importance of virtual interactions in individuals’ daily lives destabilizes the notion of “the ethnographic field linked to a place-focused concept of culture.” They argue for a reformulation of the concept of fieldwork to include multiple activities and sites in different locations and devices in order to develop “a technologically enhanced but always embodied ethnographic practice.”

Lillian Spina-Caza’s chapter, comparing children’s engagement in similar virtual and physical activities, provides a specific example of how research methods must be creatively adjusted and combined to adapt to the multifaceted nature of virtual envi-

ronments and digital technology. The chapter describes three studies building on each other and employing a wide range of methods – including content analysis, qualitative interviews, observational and cooperative inquiry techniques, and a large-scale field experiment – aimed at developing a better understanding of individuals’ perceptions of creative agency in both physical and virtual contexts. Spina-Caza’s work powerfully illustrates the productive potential of combining multiple methods and interdisciplinary perspectives and the need to remain attuned to power dynamics in research – she identifies gender as a key dimension of individuals’ experience of virtual activity.

The volume concludes with two chapters providing additional examples of interdisciplinary research, both conducted over relatively longer periods of time and employing multiple methods in varied contexts. Amparo Porta reports on her large-scale analysis of the sound environments of popular programs targeted at children in both film and television. Drawing on a semiotics approach, the chapter outlines several exploratory paths, aimed at analyzing both the content and the structure of the music, and describes the methodological instruments the author developed in order to explore the various dimensions of sound tracks. Finally, J  ssica Retis’s work on interdisciplinary approaches to understanding the relationship between media and Latino diasporic identities returns to many of the main themes running throughout the volume. Particularly noteworthy is her tackling of issues of race and class in a global context, and of the role digital technology plays in transforming “*Territorial immigrants . . . into digital immigrants* in a complex and changing process affecting both Latin Americans living abroad and their family and friends who remain in their place of origin.” From a methodological point of view, Retis’s chapter illustrates how a researcher’s long-term intellectual engagement with a broad set of research question can lead her to multiple empirical approaches and even to multiple locales – her research takes her from Madrid to Los Angeles, New York, and London. It reminds us that identities are often built in imaginary rather than physical spaces and of the importance of the media in constructing, defining, sharing, and unraveling these identities in everyday life.

To conclude, the chapters included in this volume provide resounding evidence of the dynamic and innovative character of research methods in media studies and, more broadly, of the forward-looking and interdisciplinary nature of the field. As new communication technologies are reshaping the ways in which the media operate and enter individuals’ daily routines, media studies scholars are embracing the challenge of figuring out how best to address the implications of the fact that “we no longer live with media, but in media” (Deuze, 2011, p. 137). They/we are finding that new tools are sometimes needed, while other long-established ones might require modification. They/we are learning to combine methods of inquiry in new and imaginative ways. This volume demonstrates that the history of interdisciplinarity in a field which has long, as Richard Popp puts it in Chapter 16, “borrowed liberally from fields across academia, pocketing a useful theory here or a helpful

methodology there,” has rendered media scholars particularly adaptable. They/we are, consequently, particularly well equipped to confront the challenges of our fast evolving twenty-first-century sociocultural environments.

This ability to adapt, however, does not signify a complete break from the past or from questions that have long been of concern to scholars studying the media. In a context in which we are witnessing a disturbing increase in (and tolerance for) surveillance technology and invasions of privacy, and at a time when processes of globalization are producing new forms of inequalities, it is crucial that media scholars remain focused on the core issues that have long proven central components of our field’s intellectual contribution.

Thus, the most valuable contribution of this volume’s chapters is arguably the way in which they collectively illustrate a continuing intellectual and empirical engagement with power dynamics – gender, race, class, ethnicity, global origin – even as the larger popular cultural landscape is permeated with more celebratory accounts of new technologies’ emancipatory and democratizing potential. Perhaps more than ever, media studies scholars are committed to a critical, thorough, and carefully contextualized examination of our complex and evolving media-rich environment – an examination that is attuned to multiple and diverse dynamics and to the researcher’s own position and bearing on the process of inquiry. Media studies theory continues to evolve in tandem with sharpened approaches to research methodology. This, I believe, warrants much optimism for the future of research methods in media studies.

NOTES

- 1 Media scholars remind us that all media is social media. Used to refer to some contemporary forms of digital media, “social media” is therefore rather a misnomer.
- 2 Scholars disagree on the question of when globalization “started” and whether or not it represents a complete break. They do generally agree, however, that there is “something new” about contemporary processes of global exchange when compared to earlier eras (Jones, 2010).

Media Research Paradigms

Conceptual Distinctions, Continuing Divisions

Slavko Splichal and Peter Dahlgren

ABSTRACT

Media and communication research is often believed to represent one of the youngest research areas in the social sciences, but the first essays discussing the nature and social functions of newspapers were written long before the birth of the modern social sciences. The great variety in forms of communication is also reflected in the diversity of research approaches and methods. This chapter deals with these differences and diversities in a broader perspective to demonstrate that it is not methodology itself that determines the differences in approaches but, rather, differences in methodologies that reflect more substantial (theoretical, epistemological, ideological) differences. The chapter begins with a conceptual discussion about academic fields and paradigms. It then discusses the somewhat ambiguous intellectual history of the field and its loose organizing logics. It sketches the contours of the dominant paradigm and its two main challengers over the past decades – the interpretivist and the critical paradigms – and considers some key challenges and controversies that shaped the field's earlier years. Finally, it explores a possible new matrix for structuring research in the field.

Communication as a generic human activity is characterized by an ever greater diversity of its forms, methods, and strategies from simple vernacular languages to highly formalized scientific languages. Significant differences exist between forms of communication – for example, speaking, writing, printing, electronic and digital communication, and many hybrid forms from interpersonal to mass communication – despite the fact that (technological) convergence may diminish these differences in the (near) future by providing more “unified” communication platforms and systems. In this chapter, we address the terrain of media and communication research from the horizon of prevailing paradigms. This academic field of research has been evolving since its inception and continues to do so today, with its main paradigms undergoing transformations internally and in relation to each other. We begin with a conceptual discussion about academic fields as producers of knowledge; in particular we address the notion of paradigms. From there we approach the somewhat ambiguous intellectual history of the field, and then turn to the loose organizing logics that structure it. Thereafter we sketch the contours of the dominant paradigm and its two main challengers over the past decades, the interpretivist and the critical paradigms. With these elements in place, we look at some key conflicts that shaped the field’s earlier years, and in the last section we explore a possible new matrix for structuring research in the field, building on the model for the social sciences proposed by Michael Burawoy.

Approaches, Methodologies, Paradigms

The great variety in the circumstances of mediated communication situations is reflected in the diversity of research methods deployed, from ethnographic studies, participatory observation, historical and genealogical analysis to experiments, surveys, textual analysis, and visual methods. Media and communication research ranges from idiographic approaches focusing on subjectivity, uniqueness, and comprehensive understanding of each individual or communication event, to nomothetic approaches emphasizing the importance of objectivity, general properties, and rules in a phenomenon and thus the need of generalization and necessity of probabilistic explanations. Differences between the two general approaches are not only related to theory but also to empirical research: idiographic approaches are primarily experiential (i.e., based on experience) and thus concrete, whereas nomothetic approaches are empirical in the sense of seeking for evidence to prove theoretical postulates but often abstract (i.e., abstracting from experiential situations; e.g., statistical data on abstract phenomena such as gross national product (GNP)).

Nomothetic approaches are often associated with the idea of quantification whereas idiographic approaches give preference to qualitative methods. The preference for one or other type of method often became a matter of (even ideological) controversy about the scientific merit of research, with advocates of quantitative

methods arguing that only by using such methods can the social sciences become truly scientific and their opponents who favor qualitative methods proving that quantitative methods tend to obscure the substance of the social phenomena under study which is not directly measurable.

Nevertheless, the differences in methods between the two approaches do not imply disciplinary divisions, as there is no common method(s) that could ultimately ground or substantiate a scientific discipline or field of communication. Still, it is important to critically address the methodological differences and diversities in a broader perspective to make clear that the emphasis on methodology as the site of divisions within a discipline or field of study – that is, between two approaches or any subfields within/between them – is misleading. This is because such a view suggests that it is primarily methods that divide a field or discipline, rather than “historical, economic, political, organizational, professional, and personal factors which impinge on the research process in so many ways” (Halloran, 1981, p. 1). As Merton (1945, p. 463) argued, “problems of methodology transcend those found in any one discipline, dealing either with those common to groups of disciplines or, in more generalized form, with those common to all scientific inquiry. Methodology is not peculiarly bound up with sociological problems.”

Thus, the essence and specific differences in research are not determined by method(ology) itself (e.g., differences between “qualitative” and “quantitative” methods) but, rather, differences in the methods used may at best *reflect* more substantial theoretical, epistemological (and perhaps ideological) differences and controversies underlying the research process. It is not *the* method or a set of methods that define a discipline or disciplinary “paradigm.” A paradigm is not method-driven; rather, it implies some underlying substantial theoretical and epistemological assumptions which may promote certain methods as more appropriate in pursuing research aims, and ignore or rebuff others as inappropriate. Specifically, the idea that predominantly quantitative nomothetic approaches and mainly qualitative idiographic approaches are mutually exclusive or, at least, differ in terms of scientific objectivity (e.g., the former being more objective and the latter more subjective) assumes that the unity of the sciences is grounded in sameness rather than complementarity of methods, and subsequently that the social sciences and humanities require the same kind of (quantitative) methods as the natural sciences in order to be “sciences.”

The belief that (a higher) scientific objectivity (validity and reliability) can be achieved only by the use of quantitative methods which “unfetter” research from all contextual factors does not pertain to the nature of methods and the logic of research procedures. The decontextualization of research from its social settings, which the use of quantitative methods is supposed to achieve, does not make research more objective but rather more objectionable. Separation of qualitative and quantitative methodology means divorcing method from the substance of research. Any preference for either qualitative or quantitative approaches prior to a clear conceptualization of the research problem is arbitrary. The idea of an exclusive disjunction of methods (the exclusive “or”: the use of either quantitative or qualitative methods

but not both) reflects more a prejudice against the “other” than the true nature of divergence between paradigms. Quantification gives the impression of impersonality, disinterestedness, and impartiality of research(ers) but it does not really protect it/ them from subjectivity – not only when it comes to the choice of research methods and procedures, but also and primarily in the selection of research questions and the ways in which they are addressed or suppressed in both empirical research and theory. This is not simply to say that “quantification is nothing but a political solution to a political problem [b]ut that is surely one of the things that it is” (Porter, 1995, p. x).

The selection of “relevant” theories, frames of reference, research questions, and methods is always related to the interests and values of researchers and constrained by “external” (political, ideological, financial, temporal) factors. In some cases, we may even speak of “paradigmatic blindness” censoring certain approaches and methods, when researchers “work from models acquired through education and through subsequent exposure to the literature often without quite knowing or needing to know what characteristics have given these models the status of community paradigm” (Kuhn, 1962/1970, p. 46). Such “imitative” practice may imply aprioristic preferences for either qualitative or quantitative methods; these aprioristic preferences may even match with specific paradigms. Nevertheless, it is particular concepts, research aims and questions, and (often tacit) assumptions internalized by researchers rather than specific methods that indicate and reflect a particular paradigm (or a particular political and ideological perspective).

For a complex field of study or a *metadiscipline* that cannot be defined in terms of scientific specialty and a single expert community – which we believe communication and media represent as they are interlaced with social, economic, cultural, and political contexts and thus not a unique area of any single scientific discipline – it is even less plausible that all the differences within the field could be accounted for merely by an (exclusive) set of specific research methods.

Kuhn’s concept of paradigm as “the entire constellation of beliefs, values, techniques, and so on *shared by the members of a given community*” (Kuhn, 1962/1970, p. 175, emphasis added) is inconsistent with his narrower view that “A scientific community consists . . . of the practitioners of a scientific specialty” (p. 177). Obviously, not all the practitioners share “the entire constellation of beliefs.” Moreover, if we assume that there are not very many beliefs, values, techniques, and so on shared by *all* practitioners of a scientific specialty on a global scale (which we believe is a realistic assumption), the concept of the paradigm is an empty concept. In contrast to Kuhn, we understand (disciplinary) “paradigm” in a more strict sense; it does not refer to all members of a scientific community/specialty but rather to a consistent system of (particularly epistemological) assumptions about method, object, and definition of the discipline underlying research which is rarely shared by all members of a scientific discipline or field of study. As we argue in this chapter, while paradigms have specific historical trajectories, they are not historically consecutive and mutually exclusive (in the sense that some, but not all are “scientific”), but rather mutually irreconcilable in maintaining differences and simultaneously competing *within* a given discipline or field of study (i.e., all may be “scientific”).

Ambiguity of “Media and Communication Research”

Although media and communication research is often believed to represent one of the youngest research areas in the social sciences, many social scientists of the late nineteenth and early twentieth centuries were already very conscious of the social significance of communication. Questions about the workings of communication arose in Western civilization in the early history of the “science of sciences, the science of society, of human happiness, of the *social science*,” as first named by William Thompson in 1824 when attention turned from the physical sciences and astronomy to the social and political organization of people (Thompson, 1824, p. 275). They accompanied the development of social systems and played a role in the rise of economic interests and in the success of political institutions, when communication and information became an important asset, a commodity, and a source of power.

Beyond this general historical observation about the origins of communication research, however, remains the ambiguity of the concept itself, since “communication research” may embrace pre-Socratic interests in rhetoric as well as modernism’s curiosity about the effects of media and communication in society. Equally ambiguous is the idea of “mass communication research,” which may range from seventeenth-century interests in the workings of newspapers to twenty-first-century inquiries about the Internet. However, if one considers the concept of “communication” or “mass communication” itself, the pertinent time period ranges from the late nineteenth century, when “communication” described the movement of people and words, for example, roads and the telegraph, to the mid-twentieth century, when the word “mass communication” was coined in the United States to refer to the world of media. The notion of “media,” in turn, can refer to a wide historical range of technical apparatus and procedures, from clay tablets to DVDs. With the technical convergences of the digital age, the term becomes particularly slippery: is the Internet a medium? Or many media? Is YouTube a medium? We are faced with – and will no doubt have to live with – many conceptual quandaries.

In addition, there is the concept of “research.” Understood as a systematic inquiry into a subject matter, the notion of research accompanies the rise of Western civilization, in which the curiosity of individuals expanded public knowledge and resulted in an increasingly sophisticated understanding of phenomena that affect people’s lives, like speech, writing, or language itself. Research relies on the rise of analytical practices, that is, on the nature of questions and the questioning process that have emerged over the centuries. From this angle we can specify the major intellectual concerns – the important issues – which encouraged questions about the role of communication, for instance, regarding the press, its role in society, including its effects, the uses made of newspapers, and the organizational nature of journalism. This view of media and communication research, as an integral part of a history of Western culture, identifies the field with a larger, more comprehensive and holistic vision of exploring human practices, including communication.

Long before the birth of modern social sciences, in the seventeenth century, the first essays discussing the nature and social functions of newspapers were written by empirically minded professionals who did not reflect on the conceptual issues of communication. From the mid-1800s, however, scholars acknowledged that the invention of printing introduced substantial changes in the way people (inter)acted socially. The press became “the real transmitter in the intellectual exchange between the leading organs of society and the public” (Schäffle, 1875, p. 444), differing from other forms of communication by being “thought-communication between persons who are physically separated” (Knies, 1857/1996, p. 44) and primarily by the fact that it was “a link in the chain of modern commercial machinery” (Bücher, 1893/1901, p. 216). As Tönnies (1922) argued, newspapers were from the very beginning not only intended to supplement privately mediated news in letters, but mostly to spread news intended for a larger public. Early discussions of the social consequences of technological achievements, including the rise of a dispersed audience remind us that many of the themes popularly discussed these days in association with cyberspace have their origins in the emergence of the pre-1900 communication technologies, such as the printing press, telegraph, telephone, and film. When the social sciences achieved general recognition by the end of the nineteenth century, communication became topical if not constitutive for the social sciences and for theories of society in general, particularly in the works of Gabriel Tarde, Ferdinand Tönnies, Robert E. Park, and John Dewey.

In his polemics with Émile Durkheim on the nature of “social facts,” Gabriel Tarde (1903) emphasized that “the elementary social fact is communication or the modification of a state of consciousness by the action of one human being upon another” (Durkheim & Tarde, 2008, p. 761). Tarde defined even his main theoretical concept of “imitation” as “a communication from soul to soul” (Tarde, 1897/2000). He argued pervasively against Durkheim’s contention that “A thought which is to be found in the consciousness of each individual and a movement which is repeated by all individuals are not for this reason social facts,” and accused him of ontological illusion and scholastic ontology because of his efforts to separate sociology as a scientific discipline from psychology and philosophy (Durkheim & Tarde, 2008, p. 773). Tarde also rejected Durkheim’s holistic idea of finished social wholes and promoted “methodological individualism,” focusing on the components of social interactions and practices.

Communication constitutive of public opinion – “holding and expressing opinions is an interactive process” – is one of the three key forms of the “complex social will,” which represented a conceptual cornerstone of Ferdinand Tönnies’s theory of *Gemeinschaft* (community) and *Gesellschaft* (society). The difference between community and society lies partly in their mode of communication: traditional handed-down customs and religion are typical of community, whereas public opinion that grows out of reflexive discourse between strangers and is based on reason and (scientific) knowledge is constitutive of society. Tönnies strongly believed in the possibility of the objectivity and unity of science based on interdisciplinarity but also

emphasized the need to observe humanitarian and ethical considerations. His approach to public opinion surmounted differences between the “normative” and “empirical” paradigms commonly believed to be incompatible. He combined three levels of inquiry: (1) theoretical (pure sociology *constructing* or producing theories); (2) applied (application to dynamic historical developments *deducing* from theories); and (3) empirical (*inductive* empirical research elucidating and explaining general ideas by specific examples). He advocated the use of both quantitative and qualitative methods in empirical sociology to describe, compare, and uncover regularities in social relations.

Mapping Contemporary Paradigms: Logics of Coherence

Emerging from several disciplines in the social sciences and humanities, the field of media and communication research remains heterogeneous, mirroring both its origins and the profound ongoing developments in the media landscape, as well as its sociocultural significance (McQuail, 2010, offers a map of the terrain). Over the course of several decades, it launched its own academic departments, journals, associations, and conferences. The field developed most rapidly in the United States, which for a long time defined the field and influenced its advancement globally. Today, most universities have departments offering courses and programs about the media. Academic departments go under a variety of names, emphasizing different angles on the field and reflecting national and cultural specificities, but we should be aware that with the advent of the Internet, research on “media” is being carried out in just about all fields of the social sciences as well as many in the humanities; computer sciences are also now a part of the research production within media and communication.

The rapid growth of the field brought about a variety of specializations. Research in the field is divided – though not always clearly – between an academic emphasis with social scientific or humanities horizons, and one that focuses on applied knowledge. This latter emphasis can be geared to the needs of media industries, various organizational actors that make use of the media for their own purposes (corporations, political parties, interest groups, etc.), and occupational practices within the media. The lines between the academic and the practitioner orientations are by no means fixed, and the interplay between the two can be both productive and problematic. Moreover, as neoliberal-inspired management values pervade the universities, academic research is increasingly required to demonstrate its relevance and “impact,” thereby narrowing the space for theoretical and critical efforts.

Though media and communication research is a quite disparate field, we can specify a number of logics that give some practical coherence and can serve as a rough map. The first such logic derives simply from specifying a particular medium.

Many researchers focus on, for example, television, radio, the printed press, the Internet, or social media. Others specialize still further and focus, for example, on press history or the television industry. Other studies may encompass more than one medium, for example in a case of journalism research.

A second logic takes its departure from a basic model of the communication process, and thus we can organize research according to its attention to *sender*, *message*, and *receiver*. In the context of the mass media, this yields, respectively, studies of media institutions, media output, and media audiences and/or users. Research on media institutions examines the conditions, both internal and external, that shape them, for instance questions about regulation, political influence, and organizational routines. The study of media output includes the form, content, and modes of representation, often highlighting specific genres. Research on media audiences can include analyses of the impact of specific output, the uses people make of it, and the interpretations they derive from it. Especially with the Internet and the rise of Web 2.0, the concept of audience becomes problematic, as more and more of the online traffic is user-generated (by so-called “producers”).

Third, specific topics or themes provide some ongoing coherence to the field. These themes can be broad, such as media effects or (more specifically) media effects on children. Many themes link media studies with particular topics on the wider social research agenda, such as gender and ethnicity, children, health communication, media and social movements, and media and sports. From another angle, some themes derive from particular theoretic and/or methodological developments, for example, agenda setting, media events, or media uses and gratification, and can be applied to a variety of empirical areas.

Finally, and most significantly for the character of the research itself, weaving through the above logics are some basic paradigmatic distinctions. We would reiterate that the notion of paradigm points to tendencies within the field, not to unified factions with clear demarcations. These paradigms basically reflect historically anchored differences in concerns, approaches, epistemological assumptions, and theoretical and methodological orientations; they point to distinct intellectual dispositions. The relationships between them have evolved over time, and the development of the field can be understood to a considerable extent by looking at the emergence, interface, and transitions of these major paradigms.

Tensions: The Dominant Paradigm and Its Challengers

The Dominant Paradigm: An Assemblage

In looking at the field today from a paradigm perspective, we can begin with positing what we – with some admitted conceptual looseness – term the dominant paradigm.

We choose this term to acknowledge the obvious heterogeneity of the major directions in research, yet at the same time we want to indicate that there are unifying elements in the prevailing patterns of research in the field. Thus, though the dominant paradigm encompasses a broad (and growing) array of research currents and subcurrents, and it is continually developing new approaches, it is nonetheless united in its basic adherence to traditional social scientific methodologies and approaches to theory. Its intellectual foundations are found chiefly within sociology, psychology, social psychology, and political science, with a dominance of quantitative methods. It constitutes the still hegemonic tradition of empirical research within media and communication. From about 1950 to the early 1970s, the dominant paradigm emerged, solidified, and remained essentially unchallenged. The most prominent orientation was that of media effects – to ascertain the impact of media on people's thought and behavior; the themes of violence and sex, but of course also advertising, were key areas of research (Klapper, 1960, was no doubt the most influential text in this regard). Content analysis of media output constituted the other major trajectory. This was its golden age; since then the heterogeneity of the field has increased.

Gradually, this heterogeneity of the field became problematic; debate and uncertainty began to set in, and over the years there have been a number of calls to better define the core and the boundaries of communication and media research (e.g., "Ferment in the Field," 1983; "Future of the Field I," 1993; "Future of the Field II," 1993). Questions and contentions have been aired about the range of theories and differing methodologies in the field. The vision of a unified science may still have some attraction in some circles, though it is less often asserted these days, and expectation for more field integration seems less intense. One could say that the field of media and communication research remains a somewhat unstable signifier. The large conferences suggest that a relatively harmonious coexistence between different currents prevails within the dominant paradigm (see, for example, the ICA website for current or upcoming conferences). However, in the early 1970s, two paradigmatic challenges began to assert themselves.

The Interpretivist Paradigm

A particular attribute that united the dominant paradigm was its adherence to the strict scientific model, one that builds on the premise that media research (and social research generally) should basically follow the methodological guidelines of natural sciences, using quantitative methods in particular to establish causal relationships. Two sets of critics emerged here, from the interpretivist and the critical paradigms. Both would often use the term "positivism" in criticizing the dominant, though the word was often intended as a general epithet rather than a rigorous concept from the philosophy of science. The interpretivists take the view that human beings are thinking and reflecting subjects driven by meaning; thus research must focus

precisely on the meaning of action from the standpoint of the actor. This logic can be found, for example in Weber's notion of *Verstehen*, that is, understanding as constituting the core goal of social research, clearly demonstrated also in his quest for a systematic and comprehensive examination of the press. The angle taken on communication underlined the processes of meaning or sense making over the transmission of discrete "messages" (Carey, 1989). Research explored the communicative power of symbols, the processes of rituals, the rhetoric of nonverbal gestures, and communicative contexts, among other things.

Interpretivism entered the field from several corners, including the growing orientation of social constructionism (which has since become a sort of *doxa* in some corners of the field), contributions from the humanities and from the qualitative, interpretive social sciences, and not least the rise of cultural studies. In the 1970s British cultural studies, under the leadership of Stuart Hall (see Hall et al., 1980) had begun to impact media research. The eclectic synthesis of intellectual ingredients in cultural studies – including neo-Marxism, (post)structuralism, feminism, psychoanalysis, semiotics, and ethnography – was applied not only to the media but also to a range of topics having to do with contemporary culture and society. Interpretivist strands emphasize the social construction of meaning (and identities), and the relationship between meaning, culture, and – particularly in the case of cultural studies – power. Methodologically, interpretivist approaches used conceptual toolkits such as hermeneutics, semiotics, psychoanalysis, and narratology and applied them to approaches such as ethnography, interviews, observations, and the analyses of texts and visuals. We can note that cultural studies has grown into a heterogeneous, multidisciplinary field in its own right, with contributions from currents such as postmodernism and postcolonialism, among others. Today studies of the media are only a small part of its vast concerns. As it expanded and became a global academic phenomenon mingling with many other academic traditions, the critical character of its earlier years, where issues of social and semiotic power were thematized, has not always remained evident.

The Critical Paradigm: Three Strands

The critical paradigm likewise has a mixed lineage. The notion of critique derives from G. W. F. Hegel's notion of unnecessary constraints on human freedom, which was adapted by Karl Marx and also mobilized in the various critical traditions since then in emancipatory projects that challenge various forms of domination. Thus, critique fundamentally involves normative reflection on the relations of power. In terms of media and communication research, there have been three major traditions: political economy, the critique of ideology, and theories of the public sphere. However, we should also note that there is an epistemological version of critique, which derives from Immanuel Kant and his *Critique of Pure Reason*. Here Kant underscores that our knowledge of the world is always mediated in a number of ways; we

never have direct access to it. Rather it is shaped by our sense organs, our mental processes, language, specific cultural frames of perception, social location, and so on. This version actually resonated more within the interpretivist paradigm, and can be seen as a link between the two, especially in the work of early cultural studies; its emphasis on identity, ideology, meaning, and so on intertwined critical reflection on power relationships with the development and maintenance of worldviews and particular forms of knowledge and subjectivity.

The Hegelian version of critique was stronger in the various Marxian currents that began challenging the dominant paradigm in the early 1970s, most notably the political economy and critique of ideology traditions. The political economy of the media addresses ownership, commodification, (de)regulation, policy, and the links between economics and the social, political, and cultural dimensions of modern life. The early work of such scholars as Dallas Smythe (1981) and Herbert Schiller (1975) opened up passages that scholars active today further develop (see, for example, Fuchs, 2011; Mosco, 2009). A recurring thematic here is the tension between, on the one hand, the capitalist logic of media development and operations, and on the other, concerns for the public interest and democracy. For the most part, the political economy of the media does not anticipate the elimination of commercial imperatives or market forces, but rather seeks to promote an understanding of where and how regulatory initiatives can establish optimal balances between private interest and the public good, in hopes of redressing some of the worst power inequalities and promoting the democratic potential of media.

The critique of ideology was for a while a very robust current. In the critical lexicon, ideology is not a descriptive term about party platforms or people's systematic worldviews, but refers instead to how representations of the world covertly serve the interests of some groups at the expense of others. In its more forceful versions, the critique of ideology builds on the notion of false consciousness – the systematic misapprehension of one's own (class) interests. Thus the concept is in the business of distinguishing between reality, essence, or truth, and appearance or falsehood. This of course begs the question of what the "truth" is and the term began to wobble under increasingly sophisticated scrutiny. There have been many efforts to "repair" the concept, but gradually, by the end of the 1980s, the concept was moving to the margins, and in the early 1990s it was becoming clear that the epistemologically and methodologically more sophisticated tools of critical discourse analysis (see Fairclough, 2010) were better suited for elucidating the links between representation, meaning, and power in mediated communication.

Another major – and quite familiar – building block of critical media research frames the issues of media and democracy within the concept of the *public sphere*, a notion most associated with Jürgen Habermas (1989), but one that figures in the writing of many authors (see Gripsrud, Hallsvard, Molander, & Murdock, 2010, for a collection of key texts). In schematic terms, a public sphere is understood as a constellation of institutional spaces that permit the circulation of information and ideas, as well as the formation of public opinion and communicative links between

citizens and the power holders of society. Habermas's (1989) historical analysis examines the structural evolution of public spheres as well as the character of its communicative activities, and can thus be said to straddle the base/superstructure divide. Though the Habermasian model soon raised a number of issues (see Calhoun, 1992), it has provided a strong critical foundation and normative horizon for thinking about the media, participation, and not least journalism, and has inspired countless research initiatives. The concept has some parallels with the liberal notion of the "marketplace of ideas" and similar metaphors, and today it has entered into more common usage where the problems of journalism are often discussed – though often with the risk of losing the critical foundations that derive from its intellectual origins with the Frankfurt School.

Gradually the critical paradigm became more diverse, incorporating not only post- and non-Marxian currents, but also feminism, postcolonialism, and the critical trajectories, for example on race and ethnicity and queer studies. There has been a massive amount of critical artillery aimed at media and communication, taking the dominant paradigm to task on a variety of issues. The epistemological certitude of the Marxian trajectory weakened; for many, Marxism and its emphasis on class became less of a totalizing paradigm and was seen more as one, albeit central, element, together with other currents in media and communication studies that were challenging the dominant paradigm. In the process, critical epistemological reflection became more widespread within the critical paradigm, even if some researchers more wedded to the Marxian tradition challenged what they perceived as unproductive revisionism of the critical tradition. Even today we can find issues over the relative weight to be given to the political economy versus the cultural dimensions of mediated phenomena.

Challenges and Controversies in Media Research

Since Tönnies's time, empirical research has come far in exploring (mass) communication phenomena. Systematic study of communication and media began in the United States in the 1920s under the influence of growing scientific/academic and commercial interests in this generic human ability and need, especially in its most developed and widely commercialized form – mass media. In this context, "mass communication research" found its place in traditional US academic disciplines, such as sociology, psychology, and political science. When by the end of 1950s, "communication research had come gradually to lose its place as a major concern within the conventionally recognized academic disciplines, . . . departments of journalism and other vocationally oriented faculties moved in to fill the vacuum" (Lang & Lang, 1983, p. 130). The institutional transition helped to develop a new field of research (and a "scientific discipline" for some proponents) which was largely characterized – in contrast to earlier interests in the broader societal conditions of mass media and

public opinion – by the separation of the study of mass communication from that of public opinion, a strong interest in the effects of mass media on individual behavior and preferences, and the use of quantitative methods in data gathering and analysis. The dominant paradigm had begun to take shape.

Empirical and applied research that made a very dynamic development in the early twentieth century had important and controversial consequences for all the social sciences which have begun to receive a significant position at universities, in governmental offices, and in the corporate world. Professional institutionalization of the social sciences increased interest in the reliability and validity of applied research but also often tended to overemphasize the importance of operational definitions and the empirical reliability of concepts to solve practical problems – while discriminating against the critical role of theory in steering social development. Ever higher costs of experimental and field work led professional research into dependence on the policy world and capital, and separation from civil society. Financial support from corporate foundations required researchers to shed and avoid political radicalism (rather than *any* political alignment). Critical communication research – an emerging paradigm – was challenged by the idea of a value-free or neutral research, in which the understanding of communication as a cultural transaction and symbolic interaction developed by pragmatism succumbed to a simplistic conception of communication as transmission and/or exchange.

Paradigmatic challenges to media research came into sight most often in the periods of invention and/or dominance of a new quantitative method or approach in empirical communication research, but methodological controversies always reflected broader issues of the nature and function of media (research) in society. We will briefly address three such historical challenges related to methodological innovations:

- the invention of polling and its critiques;
- quantitative versus qualitative content analysis;
- audience research and the dispute on “administrative” versus “critical” research.

Polling: The Separation of Public Opinion from Communication?

The invention of polling in the late 1920s has significantly influenced conceptualizations of public opinion and its role in (mass) societies. Furthermore, it typically divided the academic community into those who admire polling as a tool to make democratic life more efficacious and its critics who argue that it has undermined it fatally. At first glance the main issue at stake in the controversy on “measuring public opinion” may seem to be the *quantification* of public opinion by using sampling methods, data gathering procedures (e.g., attitude scales), and statistical analysis. However, as it will be made clear, the controversy goes beyond inaccuracies in

sampling methods and predictions and primarily refers to the ontological and epistemological status of public opinion versus polling.

The controversies around polling can perhaps be best illustrated with two polar attitudes toward “the science of measuring public opinion,” as Gallup called the innovative research procedure in the collection of interview response data.¹ At one extreme, Herbert Blumer blamed polling for the loss of the generic subject as it was not able to “isolate ‘public opinion’ as an abstract or generic concept which could thereby become the focal point for the formation of a system of propositions” (Blumer, 1948, p. 542). Instead of identifying public opinion as an object of study and contributing to its better understanding, according to Blumer, polls actually “constitute” the object of study (“public opinion”) ostensibly in the process of sampling, data gathering, and aggregating. The operationalistic understanding of public opinion as an aggregate of equally valid opinions by independent individuals collected from a random sample of population suggests that a public and, thus, society exists as a mere aggregate of disparate individuals in contrast to the actual “organic” operation of public opinion in society. Furthermore, the high predictive validity of *election* polls (in predicting outcomes of elections) cannot be “extrapolated” to the universal validity of polling because even the most accurate *prediction* cannot be swapped for *explanation*, and the accuracy of prediction of election results in election polls cannot be generalized and transferred to any kind of polling.

At the other extreme, Osborne and Rose praised polling precisely for having produced public opinion as a new social phenomenon which “is created by the procedures that are established to ‘discover’ it,” thus making polling similar to the successful natural sciences in creating new phenomena (Osborne & Rose, 1999, p. 382). In other words, according to Osborne and Rose, public opinion was not observable and did not exist in empirical terms prior to the development of interview response data gathering procedures. Public opinion is the result of, and is identical to, sampling, data gathering, and aggregating.

Before the advent of polling, the social sciences made rather unsuccessful attempts at scientific operationalization of the normative concept of public opinion. With polling, however, a satisfactory degree of empirical validity has been achieved, as its prophets and pollsters believed. Gallup praised polls for creating a new momentum to strengthen democracy. He believed, exaggerating James Bryce’s enthusiasm, that with polls “the will of the majority of citizens can be ascertained at all times” (Gallup, 1938, p. 14). Following Bryce, Gallup defended an ostensive definition of public opinion as a simple “aggregate of the views men hold regarding matters that affect or interest the community” (Gallup, 1957, p. 23). Polls ought to compensate for the growing limitations to citizens’ political participation in parliamentary democracy. Gallup defined polling results as a “mandate from the people” to the government and suggested that polling might help re-establish the town meetings of antique Greece on a national scale. Polling was believed to provide a democratic counterweight to the growing independence of political elites and the separation of representation from popular rule.

The issues of empirical verifiability and the reliability of polling dominated scholarly debates on public opinion to such a degree that, in the 1930s, polling reached the position of the dominant public opinion paradigm, thus shoving aside the traditional normative conceptualizations of public opinion. "The advent of so-called 'scientific polls' during the 1930s has gone far toward solving the problem of ascertaining quickly, economically, and accurately the states and trends of public opinion on a large scale," wrote Childs (1965, p. 45). Polls provided information about individuals' attitudes that is relevant to the political process and predictions of their voting behavior, but also commercially relevant information on the purchasing habits and power of consumers, and on the relationship between advertisements, consumer preferences, and buying decisions, which became a key area in market research.

However, while pollsters hailed polling as part of a solution for the growing democratic deficit, its opponents saw in it a serious threat to democracy – not only did polling not stimulate public discussion, but it even prevented and/or replaced it. Moreover, pollsters were criticized for their erroneous premise that public opinion expressed by a majority in polling should be simply followed by political action in the same way as merchants follow the results of consumers' research. Several critics believed that the main purpose of polling by the government could be manufacturing citizens' opinions and changing those which were not congruent with the course of action, thus marginalizing the power of public opinion.

Controversies on polling are essentially political and theoretical rather than methodological. The specific aims of polls are not their intrinsic functions but are defined by their users and observers. It may well be that polls had been initially designed as a research procedure to "measure public opinion." Whether or not public opinion is "measurable," however, is not a methodological but a theoretical issue. Similarly, the embeddedness of polls in the political system resulted in specific *political* functions (e.g., "illuminating the state of public opinion for the benefit of the representatives of the people," according to Gallup (1971, p. 227)), which were assigned to polling independently of its methodological drift.

Content Analysis: Issues of Empirical Reliability and Theoretical Validity

As early as in the late nineteenth century, before the first polls were conducted, a sort of "quantitative newspaper analysis" was used to show how the contents of New York newspapers had changed between 1881 and 1893 (Krippendorff, 1980, p. 14). Much earlier, however, the first *qualitative content analysis* appeared – in censorship. Censors had the task of analyzing written materials in a systematic way to discover forbidden ideas hidden in texts so as to prosecute their authors, as decreed by the ruling secular or ecclesiastic powers. Plato was the founder of the aristocratic idea of censorship that has resounded for more than 2,000 years. In *The Republic*, he substantiated the necessity of censorship to prevent narrators and poets from making

“an erroneous representation . . . of the nature of gods and heroes” which young people would not be able to understand (Plato 360 BCE/1901).

With the development of the social sciences, content analysis became one of its most important methodological tools. At the beginning of the twentieth century, in a speech to the German Sociological Association, Max Weber called attention to the need for a systematic and comprehensive examination of the press, starting “with scissors and compasses to measure the quantitative change of newspaper contents . . . From these quantitative analyses we will proceed to qualitative ones” (Weber, 1910/1979, pp. 151–152). Unfortunately, Weber’s ambitious project did not succeed for a variety of reasons, and World War I ultimately prevented its realization (Hardt, 1979, p. 183).

Content analysis entered its golden period during World War II, with the US government-sponsored War Communications Research Project aiming to analyze enemy propaganda and the “language of communism.” The book on *Language of Politics: Studies in Quantitative Semantics* (Lasswell et al., 1949), which resulted from the project, inspired many communication scholars to get to grips with quantitative content analysis in the decades to follow. Lasswell insisted on the quantitative approach in order to overcome severe “limitations of qualitative analysis,” such as imprecision and arbitrariness. He argued that the quantitative analysis of political discourse would both advance political science and contribute to policy gains (Lasswell, 1949, pp. 40, 52). Following this reasoning, Bernard Berelson contributed a definition of content analysis as “a research technique for the objective, systematic and *quantitative* description of the *manifest* content of communication” (Berelson, 1952, p. 18, emphases added), which dominated the field for quite some time. It not only excluded qualitative approaches to media contents but also limited analysis to “‘manifest content’ [which] exists in the form of black-marks-on-white” (p. 19).

It should be added, though, that Berelson restricted the validity of quantitative content analysis to the sorts of standardized textual material one can find in newspapers, and he warned: “The analysis of manifest content is applicable to materials . . . where understanding is simple and direct . . . Whenever one word or one phrase is as ‘important’ as the rest of the content taken together, quantitative analysis would not apply” (Berelson, 1952, p. 20). Taking this limitation seriously would, according to Berelson, make all interpretive genres with nonstandardized forms and nonconventional contents – where “different members of the intended audience” do not “get the same understanding from them” – entirely inappropriate for “quantitative analysis of black-marks-on-white” (Berelson, 1952, p. 20). The obvious problem is that when texts² may be understood or “decoded” in a variety of different ways, the principle of empirical reliability of (de)coding (i.e., the need that all coders understand and code each text in the same way) may violate the principle of validity by reducing different readings to the lowest common denominator that still promises reliable quantitative coding. Even if quantitative coding is reliable, it alone does not guarantee valid results. Kracauer (1952–1953) questioned the exclusive use of quantitative content analysis on the ground of its implicit assumption that the frequency

of appearance of a characteristic (e.g., a word or a class of words) is taken as the indicator of its importance: the more often it appears, the greater its importance on the whole.

Kracauer emphasized the need to combine the two approaches because “qualitative analysis” and “quantitative analysis” do not refer to radically different methodologies:

Quantitative analysis includes qualitative aspects, for it both originates and culminates in qualitative considerations. On the other hand, qualitative analysis proper often requires quantification in the interest of exhaustive treatment. Far from being strict alternatives the two approaches actually overlap, and have in fact complemented and interpenetrated each other in several investigations. (Kracauer, 1952–1953, p. 637)

Hence, a prejudiced trust in the validity of quantitative content analysis ignores the important role that qualitative (interpretive) examination may play in text analysis and communication research in general.

Administrative Research and Empirical Critique

Theodor Adorno’s critical reflection on lessons taught in the Princeton Radio Project (1938–1941)³ still has relevance today for the discussion on the (potential) political implications of empirical communication research. Part of the comprehensive empirical Radio Project was devoted to radio listening habits. Adorno’s inside experience with the project suggests that, even compared to the most radical critical theories (in terms of either existing knowledge or prevailing politics), applied research is much more (and more directly) affected by institutional constraints and temptations to yield to conditions defined by funding institutions. This could even lead to the conclusion that *any* empirical and particularly quantitative research, by necessity, reduces the level of criticism theory can provide, but such a conclusion would be premature, as Adorno admitted.

In his critical appraisal, Adorno indicated that there was little room for critical social research in the framework of the Princeton Project.

Its charter, which came from the Rockefeller Foundation, expressly stipulated that the investigations must be performed within the limits of the commercial radio system prevailing in the United States. It was thereby implied that the system itself, its cultural and sociological consequences and its social and economic presuppositions were not to be analyzed. (Adorno, 1969, p. 343)

Adorno was critical of the implied and perhaps unconscious conformity of professional researchers who tacitly completed research orders and did not dare to question the reasons and consequences of such an investigation, its aims and the methods used to achieve them, the goals and interests of individuals and social groups chosen

as research units, and researchers' own actions within it. Referring to the part of the project dealing with music listening, he identified two kinds of questions representing "administrative technique" which are effectively used to manipulate the masses: (1) questions directed toward the reactions of audiences when exposed to certain kinds of programming, for example, "If we confront such and such a sector of the population with such and such a type of music, what reactions may we expect?" or "How many sections of the population have been brought into contact with music and how do they respond to it?" (2) questions directed toward the efficacy of research procedures, for example, "How can these reactions be measured and expressed statistically?" (Adorno, 1945, p. 208).

Such questions resemble questions asked in a laboratory experiment or market analysis where research objects (units) are exposed to different treatments (variables) to find out how effective they are. If experiment or analysis is successful, researchers can recommend the treatment to be applied in order to produce the effect we want to achieve in practice. In terms of "how certain aims can be best realized under the given conditions," that is, how effective research techniques are used to manipulate the masses, Adorno differentiated between directly "*exploitive*" research (e.g., aiming at selling certain commodities) and "*benevolent* administrative research" (e.g., how to bring *good* music to as large a number of listeners as possible).

An alternative to these manipulative or administrative approaches would be a commitment to design research as social critique, that is, to question the aims "imposed" on research, or at least their successful accomplishment under given conditions:

One should not study the attitudes of listeners, without considering how far these attitudes reflect broader social behavior patterns and, even more, how far they are conditioned by the structure of society as a whole. This leads directly to the problem of *social critique* of radio music, that of discovering its social position and function. (Adorno, 1945, p. 209)

Although Adorno later explicitly contradicted the interpretation that he rejected empirical social research and underlined that he "consider[ed] these procedures not only important within their own sphere but also as appropriate" (Lang, 1979, p. 93), his attitude toward the use of quantitative methods in empirical research remained uncertain. His suggestion that one possible indicator of administrative research be the statistical measurement of survey response data certainly helped the qualitative–quantitative controversy continue through the decades.

Controversies over administrative and quantitative research in communication vivified in the 1980s after Smythe's and Van Dinh's (re)conceptualization of "administrative ideology" as "the linking of administrative type problems and tools, with interpretation of results that supports, or does not seriously disturb, the status quo" (Smythe & Van Dinh, 1983, p. 118). According to the authors, administrative ideology implies not only "administrative type *problems*" but also "administrative type *tools*,"

in addition to a specific way of interpreting research findings which “supports, or does not seriously disturb, the status quo.” In contrast to Merton’s argument that problems of methodology neither are specific to any single discipline in the social sciences nor imply a particular content of a theory, they seemed to believe that “tools” are specifically tied up with “problems.” Pursuing this idea, Smythe and Van Dinh operationalized “administrative research” by equating it with “quantitative research”:

Under administrative research, the first type of research is for simplicity called “quantitative.” It includes market research . . . it serves the private corporate interests . . . Survey research, conducted with rigorous standards for sampling, variance estimates, and control (but not elimination) of biases involved in questionnaire construction and interview and coding techniques, would also qualify as quantitative administrative research. (Smythe & Van Dinh, 1983, pp. 118–119)

The operationalization tacitly slides from “market research” to “quantitative administrative research” without providing any substantiation for it. While “market research” (with research questions and aims subject to commercial interests and profit) represents a specific materialization of “administrative ideology,” this representation cannot be transferred to the relationship between quantitative methods and administrative ideology, so that “quantitative methods” would indicate “administrative ideology.”

Reducing the “administrative–critical” relationship to “qualitative–quantitative” misplaces the “theoretical–empirical” issue. As the empirical methods are instrumental solutions to the problems of gathering, processing, and interpreting information (data), the choice of specific methods should depend on the subject and the aim of the research. The decisions as to whether it is appropriate to choose qualitative and/or quantitative methods should be based on the respective probabilities of obtaining the evidence being sought, and no method can be *a priori* excluded as inappropriate, whether quantitative or qualitative. Unfortunately, research practice is often far from such an ideal state.

One of the central issues of empirical research is the theoretic ability of a researcher to differentiate between the *quantitatively prevailing* and the *essential* characteristics of objects under study. The essential characteristics of a social phenomenon or fact are never determined by the remains of the old in it, although quantitatively they still dominate, but by the elements of the new, that is, by the direction and aim of the development. In the early phases of the development, the new never appears as quantitatively dominant or as an average, but rather as an “exception” for which only a more thorough and theoretically based research can show that it is actually not a mere coincidence but rather a rule, a result of general development. Yet the task of empirical research may not be reduced to revealing just new (e.g., in contrast to prevailing) phenomenological forms. For social research and policy as well, it is essential to discover the conditions which (may) lead to the affirmation of the new

and those which prevent or hinder its further development, and to conceptualize the relationship between them.

Social Media Research: A New Paradigm?

Gabriel Tarde had problems persuading Durkheim that (interpersonal) communication is a fundamental social fact, but in the age of computer-mediated communication and social media, this is beyond any doubt. Social network sites (SNS) – “web-based services that allow individuals to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system” (bojd & Ellison, 2007) – became a major object of study in communication research not only because of their popularity but also because of the unprecedented abundance of self-generated data they provide. In traditional research, the data gathering process is clearly separated from the process of communication as the object of study: surveys and text analyses are used to provide data on the already existing (f)acts, whereas the contradictory nature of polls (a tool or an object of study?) was a major source of scholarly controversies.

Internet interactions, links and profiles, and mobile phone uses represent an entirely new mode of communication that combines the timeliness of speaking and the endurance of writing. Moreover, the digital(ized) communicative acts generate “surplus” information on users’ online activities that can be tracked down, explored, and used (and eventually even sold) by those not participating in interactions. Without the consent and even knowledge of the participants, rich data sets can be created to study patterns of calling and receiving phone calls, sending and receiving messages, downloading and uploading files, (un)friending and (un)liking on the individual and aggregate levels. This kind of surveillance, coupled with the massive amounts of so-called big data that it generates, raises serious ethical and legal issues. These issues have to do not only with the practices of research; more fundamentally, the collecting, analyzing, selling, and strategic use of such data for commercial or political purposes become problematic for the life of democracy (see Oboler, Welsh, and Cruz, 2012).

What is more, new modes of digital communication also challenge the belief that it is possible to clearly separate methodology from theory. Merton was once critical of inductive empirical research using already existing data sets in which “observations are at hand and the interpretations are subsequently applied to the data,” because in that process an interpretation can always be found to “fit facts” (Merton, 1945, p. 468). Before the advent of computer-mediated communication, the “data at hand” were always generated independently of communication processes under study; they were usually “secondhand” data created in previous research. In digital communication, however, the data sets existing prior to our study consist of “footprints” of personal information participants leave online while communicating, and make them

(often unwittingly) available to others. This information is generated automatically by the software enabling communication itself and thus cannot be prevented.

We do not mean to say that the rise of digital modes of communication made communication research methodology-driven. On the contrary, given the ever tight connection between theory and methodology, these developments make critical reflection and development in regard to theory all the more imperative.

For a Reconstituted Matrix of Research

In 1996 what is called the Gulbenkian Commission on the restructuring of the social sciences, chaired by Immanuel Wallerstein, presented its report, *Open the Social Sciences*. In brief, the report called for a leaving behind of what the authors perceived as outdated disciplinary divisions, vested interests, and dead-end epistemologies. It advocated a unification that would also interface fruitfully with the humanities and the natural sciences. While there was much merit to the report, it also suffered from a utopian universalism and left unanswered such basic questions as for whom and for what the knowledge was meant. In the years since then there have been a number of discussions and debates about it. One such intervention is by Burawoy (2007), on the tenth anniversary of the report. He posits that it is urgent to focus precisely on the questions of for whom research knowledge is intended and for what purposes. In pursuing these questions, he suggests that we distinguish between knowledge production that is aimed at academic audiences – our colleagues – and at others, in the social worlds beyond the university. In regard to the purposes of research, he says we should ask “whether the knowledge concerns the determination of the appropriate means to pursue a given, taken-for-granted end, or whether it involves a discussion of those very ends themselves: that is whether the knowledge is instrumental or whether it is reflexive” (Burawoy, 2007, p. 139).

From this line of reasoning emerge four types of knowledge that define a field of research. We have adapted the names of the categories to better fit the circumstances and intellectual history of media research discussed above, and arrived at the four categories presented in Table 1.1.

This matrix, with its four forms of knowledge, would seem to fit the field of media research rather well. We need not concern ourselves with any grand universalizing synthesis of the field; it will no doubt continue with its dominant paradigm and

Table 1.1 Division of disciplinary knowledge

	Academic audience	Extra-academic audience
Instrumental knowledge	Professional	Administrative
Reflexive knowledge	Critical	Policy

various challengers to it. What the proposed matrix offers is a way to depict and not least to legitimize different forms of knowledge for different purposes, which takes us beyond the constricting confines of a unitary/positivist model of the field.

Professional knowledge is for the professional, that is academic, audience. It is the knowledge aimed at ourselves, our colleagues, who have the task of further developing the knowledge that the field embodies. Professional knowledge is instrumental in the sense that it follows established patterns of theorizing and methodological approaches to find out new things. It will continue to be characterized by heterogeneity, coexistence, and disputes over theory and methods. Some specialized corners may become (or remain) incommensurable with others, but we will simply have to live with that and not let the absence of a unifying approach or clear boundaries to the field subvert the overall production of new knowledge.

Administrative knowledge can take many forms in that there are many groups within the extra-academic audiences that have need of research-based knowledge. We carry forward the insights gained from the decades-old discussions about this form of knowledge, for example that it is not *a priori* quantitative or qualitative in character, and that it can be utilized for benevolent as well as exploitive purposes. Administrative knowledge is geared to the needs defined by the clients; it is instrumental in that its utility is defined by specific goals or ongoing tasks of the clients. Within civil society there are many groups, networks, and organizations, which in various ways have interests that relate to the media. Associations of television viewers, concerned parents, and advocacy groups focused on advertising, political, and corporate interests all have interests in the media that can be served by research.

The groups for whom administrative knowledge is most continuously salient are no doubt the many cadres of personnel and management working within the media, from advertising and journalism, from television production to social media strategists. There is an ongoing demand from media practitioners for up-to-date research on the media and their relations to social, economic, political, and cultural domains. Certainly there can arise some conflicts of interest in regard to public knowledge: advertisers want to reach target audiences, while many such audiences (or their parents) may be more interested in how to avoid or resist media strategies. These conflicts too will simply have to be dealt with as they arise; they do not inherently destabilize this form of knowledge.

Policy knowledge is a reflexive form in that it involves consideration of norms, values, and practices in the media landscape. Policy in the media field is shaped by the intersection of normative considerations with the specific interests and actors involved, such as the state, commercial media institutions, the advertising industry, media production organizations, hardware manufacturers, political parties, citizens' groups, the "common interest" and democracy itself. Research on policy can focus on specific services, how they are to be financed and regulated, the perceived needs of various groups, and involve a normative balancing of conflicting interests. Integral to the policy process are various forms of public hearings where not just stakeholders but the general public are often entitled – at least formally – to be witnesses and

participants. Yet, we must acknowledge that research into policy (see Just & Puppis, 2012, for a recent treatment) can at times take on an instrumental character, and this shift in character may well have to do with the power relations involved. Thus, powerful groups may pursue their strategic interests via policy knowledge, eroding its reflexive character and pushing it toward administrative knowledge, with its administrative (and not always benevolent) character. The struggle becomes one of thereby trying to maintain the reflexive character of policy research – and here its links with critical knowledge (e.g., political economy) becomes essential.

Finally, critical research knowledge draws upon the Hegelian and Kantian traditions to reflect on power relations and justice, as well as what we know, what we don't know, and what we might know. We view critique as an essential phase or moment of research, and the kind of knowledge it produces can promote re-evaluation, rethinking, and redirection. It facilitates adjustment of our understanding of both ongoing professional research but also of the social world more generally – which is always in transition. Critical knowledge can thus feed into professional knowledge as well as policy knowledge. Its major “collision” tends to be with administrative knowledge, where clients are reluctant to have their goals challenged by critical researchers – mirroring again a continued tension in the knowledge produced by media research.

If we apply this matrix very briefly to the newer terrain of social media, we can note that there is a concerted effort not just from our field but from many disciplines to generate professional knowledge about its character, use, consequences, and contingencies. At the same time there is a massive generation of administrative knowledge geared to deploying social media for marketing and advertising. There is also some policy knowledge being produced by researchers, but we would suggest that far more is needed, especially to gird the reflexive discussions about how such media are to be supported, regulated, made accountable, and how the freedoms associated with them are to be protected. Critical research is emerging, addressing not least questions of political economy, such as ownership, control, and financing, as well as problems to do with surveillance, privacy, and copyright. These initiatives can interface quite neatly with policy research, but hopefully they will also impact on the professional knowledge generated – which often reflects the perspective of the dominant paradigm. We can expect these force fields to be with us for some time.

NOTES

- 1 For a more detailed account of these controversies see Splichal, 2012.
- 2 Texts – “literary and visual constructs, employing symbolic means, shaped by rules, conventions and traditions intrinsic to the use of language in its widest sense” (Hall, 1975, p. 17) – are artifacts that we use to make meaning of and from; they include not only printed documents but also radio and television programs, movies, documentaries, shows, websites, and many others.

- 3 Under the lead of Paul Lazarsfeld, the project was launched at Princeton University in 1937 and later moved to the Columbia University's Bureau of Applied Social Research.

The Challenge of Media Research Ethics

Kevin Healey

ABSTRACT

This chapter provides an overview of basic theoretical and logistical issues related to the ethical conduct of media research. A brief opening section places media studies within the broader history of research ethics, including the formation of professional codes and ethics review boards. The body of the chapter explores key concepts such as privacy, deception, and informed consent through a handful of exemplary case studies. Cases highlight issues associated with common methods including survey, experiment, ethnography, content analysis, historical and policy research. Special attention is given to the ways that emerging media technologies and contemporary critical/cultural approaches raise fundamental questions about established ethical frameworks.

Who Cares About Research Ethics?

An undergraduate student is researching the prevalence of pornography in online bulletin board systems. If some of the user data for these bulletin boards is publicly available, is it okay for him or her to access it for research? If some of these users

have taken measures to protect their privacy, is it fair for him or her to suggest that they may be hiding their interest in child pornography?

A team of professional researchers is investigating how community radio in Ghana can facilitate local initiatives to address climate change. Are they damaging the local broadcasting stations' image of political neutrality by involving them in research aimed at social change? How can they protect the anonymity of local community members, whose criticisms of local authorities may be aired on local broadcasts?

These real-world examples, both from published research articles, only hint at the range of ethical issues faced by media researchers. This chapter provides an overview of these issues as they arise in various methodological contexts – from online surveys to post-ethnographic field studies. In covering this wide range of approaches, this chapter has two main goals. The first is pragmatic: to provide an introduction to basic ethical concepts and research protocols, highlighting how they are complicated by the emergence of new media technologies. The second goal is critical: to question some of the underlying values and ideologies that guide media research projects and the institutional bureaucracies that govern them.

Does all media research involve ethical issues? At first glance it may appear that only research involving human subjects in an experimental setting would require institutional approval or adherence to professional codes of ethics. Scholars might assume that journalism, historical research, creative work, or database research are exempt from the purview of ethics review boards or established professional codes. In fact, while there are many professional media research organizations, not all have articulated formal codes of ethics. But as Jones (2004) notes, many areas in the humanities have come under increased scrutiny as the “mission creep” of ethics review boards has brought previously exempt lines of inquiry under the purview of institutional governance. Perhaps for this reason, some scholars suggest that a shift toward more formalization is underway – as indicated, for example, by the introduction of a code of ethics in 2008 by the Association for Education in Journalism and Mass Communication in the United States (Wimmer & Dominick, 2011, p. 80).

Despite the lack of formalization across media research organizations, most scholars agree that there are several basic principles that are common to all research methodologies in all fields. At minimum, researchers should: insure that subjects are free to enter and exit the study; protect their subjects' privacy; provide benefit rather than harm; and treat all persons with respect (Wimmer & Dominick, 2011, p. 67).

However obvious they may seem, as Christians (2007) suggests, the articulation and formalization of such foundational principles is worthy of ongoing debate. The search for universal principles always takes the form of an unfinished conversation, especially as emerging media technologies and new theoretical paradigms arise to challenge established methodologies and institutional frameworks.

With a broad historical and philosophical understanding of ongoing debates in research ethics, scholars can conduct their own projects more effectively and responsibly, shaping the future of their fields as well as the institutional structures that simultaneously support, fund, and regulate them. Moreover, by developing a more

sophisticated ethical sensibility, researchers can design and embark on projects that have a practical and lasting impact on the lived experiences of people at the local, national, and international level. Whether conducted in academic, commercial, or governmental contexts, media research should have as its goal the enhancement of human flourishing. The discussion that follows serves as an overview of – and an invitation to join in – this important conversation.

Three Types of Ethical Questions

In addressing the topic of ethics in media research, there are at least three different types of questions we can ask. These range from the narrow and pragmatic to the broad and philosophical. As the following sections demonstrate, they overlap in complex ways and – depending on the chosen line of research – media scholars will devote different amounts of energy to each. But responsible media scholarship requires familiarity and facility with all three.

Questions of Motivation and Intent

The first type of question addresses the research project as a whole, assessing its purpose, motivation, goals, funding sources, or its presentation to other scholars and the general public. Is it okay to conduct psychological research with children in order to increase the effectiveness of advertising campaigns? Is it okay to take money from the government or special interest groups to fund your research? As discussed below, even when motivated by a noble goal – such as reducing violence or improving working conditions – the pursuit of such goals may produce unintended consequences. Researchers or policymakers may be tempted to overstate research results to rally support for a particular social or political cause, to satisfy the demands of funding sources, or simply to bolster their own research arguments. Such problems are known as “citation bias” or “outcome reporting bias.” Engagement with these types of questions reminds us that our research is often a reflection of our cultural values and social location (e.g., our political affiliations, economic background, or gender). As Thomas (2004) suggests, such questions highlight our “conflicting allegiances to subjects” and keep us aware of “where our ethical loyalties lie” (p. 189). Beyond insuring accuracy, integrity, and credibility, an awareness of these questions can help to insure that research has a positive social impact.

Questions of Conduct and Procedure

The second type of question, which is more narrow and pragmatic, has to do with the conduct of research itself. When is informed consent necessary? How do I avoid

influencing my research subjects? When can I use publicly available data? Under what conditions is it acceptable to withhold information from subjects about the research in which they are participating? Answering these types of questions requires familiarity with key ethical concepts such as deception, privacy, harm, and power. Even with such familiarity, there are significant differences of opinion on these types of questions. For example, deception has been used frequently in laboratory research. In fact, half of the published social psychology research articles from 1969 to 1979 used deception (Greenberg, Eastin, & Garramone, 2003, p. 306). But many scholars believe deception is never acceptable and set aside research questions that would require its use.

Failure to address these pragmatic questions effectively can have a range of consequences. On the most basic level, an ethical breach may corrupt the accuracy of one's research data. Beyond that immediate concern, ethical breaches can tarnish the research profession as a whole, making people less likely to participate in ongoing studies (Wimmer & Dominick, 2011, pp. 65–66). Indeed, research indicates that subjects who are intentionally deceived during a research project tend to become more skeptical about future participation in other projects (Wimmer & Dominick, 2011, p. 72). As Thomas (2004, p. 188) notes, “a single egregious violation by one researcher poisons the credibility of others as well.” More importantly, ethical breaches can endanger subjects psychologically, physically, and even, in the case of online data aggregation, financially.

Questions of Epistemology and Ideology

Professional codes of conduct and the protocols of ethics review boards are designed primarily to address the first two types of questions. However, a third type of question, broader in scope than the others, problematizes the epistemological and ideological orientations that form the backdrop of any research project as well as the institutional structures that govern them. What exactly is research? Is knowledge something that can be “produced”? How do our definitions of research, and our structures for governing it, reflect particular cultural and ideological values? Is ethics simply a matter of following agreed-upon rules, as the protocols of ethics review boards seem to suggest? Can a fixation on rule making undermine rather than insure ethical conduct? Does “positivist” research continue the patriarchal and imperialist legacy of the Enlightenment? Such questions suggest that all research projects, and all institutional structures that intend to insure their ethical soundness, are implicated in ethical and philosophical debates that are far from settled.

All research has an ethical orientation, as do the organizations that provide guidelines and restrictions for its conduct (Wimmer & Dominick, 2011). Such orientations draw from a broad range of ethical theories. Deontological theories, epitomized by the work of Immanuel Kant, outline a rule-based approach to ethics. They provide precepts or codes of behavior for researchers to follow. This approach is typified by

ethics review boards. As discussed below, while the provision of clear guidelines has its benefits, this approach can lead to situations where researchers follow rules even when they seem “irrational,” on the presumption that “an ethical outcome will follow” (Thomas, 2004, p. 193). By contrast, teleological theories – which draw from the utilitarian philosophy of John Stuart Mill – focus on the end result of behaviors. Such approaches assume that hard and fast rules do not work well in all situations, and are therefore often in conflict with rule-based approaches. These two approaches inform the bulk of traditional academic research in the “natural” and social sciences, including much research in media studies and communications.

Other theoretical approaches question these Enlightenment-style theories on the grounds that they perpetuate cultural biases. Relativistic, pragmatic, postcolonial, and feminist communitarian approaches provide alternate approaches to ethical and scientific inquiry by explicitly addressing issues of social and cultural difference. As discussed below, theorists like Norman Denzin and Clifford Christians suggest that the epistemological and ethical frameworks that inform ethics review boards are ideologically at odds with those of many emerging scholarly paradigms, especially those that highlight the political dimension of academic research and frame scholarship in terms of a “social ethics of resistance” (Christians, 2007, p. 56). From such perspectives institutional committees embody the very ideologies that critical scholarship seeks to question. Perspectives on how best to address this tension are addressed in this chapter’s concluding sections.

A Brief History of Ethics Review Boards

While a distinct area of inquiry in its own right, media research is situated within the broader history of research in the natural and social sciences. The ethical issues emerging from research in these other areas – especially medical science – have had a lasting impact on all areas of academic research. The widespread presence of ethics review boards in academic and governmental institutions around the world is among the most important impacts of this history. Since many forms of media research – historical, experimental, ethnographic, or otherwise – fall under the purview of ethics review boards, and since their influence is felt even among humanistic scholars, it is important to understand the historical impetus for their formation as well as the problems caused by their institutional presence. In this section, the development of institutional review boards (IRBs) in the United States will serve as an illustrative case study that highlights the general impetus behind the development of similar structures around the world.

The prehistory of IRBs in the United States is marked by some of the most egregious ethical breaches in the history of modern science. Some of these breaches occurred under the auspices of Nazi rule in Germany, while others were perpetrated by the federal government of the United States. While the US government had

conducted experiments on children and the mentally ill during World War II, Nazi researchers went much further by shooting, poisoning, torturing, and infecting patients with disease. After criminal proceedings were instituted and Nazi physicians sentenced to prison or death, American doctors developed a set of guidelines for medical research known as the Nuremberg Code. Though not legally binding, this code clarified the principle of informed consent.

In addition to these Nazi atrocities, the exposure in the early 1970s of the US Public Health Service's notorious Tuskegee syphilis study – in which researchers studied the progression of the disease in black men without informing them of their condition or providing treatment – prompted the formalization of regulations for government-funded research. In the mid-1960s, the US Public Health Service had already begun to require independent review of research grants as a condition for funding. Soon after that, the Department of Health, Education, and Welfare outlined formal rules and procedures for informed consent. Prompted by public outcry over the Tuskegee experiments, the National Research Act of 1974 outlined specific provisions for the establishment and formal regulation of IRBs. A newly formed federal commission issued the so-called Belmont Report, which stipulates that the protection of human subjects hinges on three principles: respect for persons, also known as informed consent; beneficence, which requires that researchers “do no harm”; and justice, which entails a fair distribution of the benefits and burdens of research. In the early 1980s these regulations, which mainly targeted biomedical and behavioral research, were “softened” to accommodate common types of social science research (Wimmer & Dominick, 2011, p. 76). Later regulations focused on problems such as plagiarism and the falsification of data (Christians, 2007, p. 54).

Today, there are hundreds of IRBs at research and educational institutions around the United States whose primary task is to insure adherence to federal regulations outlined by the US Department of Health and Human Services (DHHS). Technically, these regulations apply only to research conducted with or funded by the DHHS. Most nonexperimental research projects are exempt from these rules. The federal government offers decision charts to help researchers understand whether their research requires IRB approval (DHHS, 2004). IRBs differ among institutions, however, and many have more stringent rules than those outlined in the federal standards (Greenberg et al., 2003, p. 315), including rules that impact nonexperimental, qualitative, historical, and participatory forms of research. Therefore, regardless of the nature of one's research, it is important for scholars at US institutions to know the specific protocols that apply to their work.

The historical development and ongoing debates about IRBs in the United States are echoed internationally. For example, counterparts to the Belmont Report, which is a foundational document in the US context, can be found in reports from Norway's National Committee for Research Ethics in the Social Sciences and the Humanities (NESH) and the Swedish Council for Research in the Humanities and Social Sciences (HSFR). The Swedish Research Council articulates guidelines for informed consent in much the same manner as the DHHS in the United States (Sveningsson Elm, 2009, p. 71). Ethics review boards at non-US institutions operate in similar ways to IRBs,

and in some cases incorporate standards from US federal agencies. For example, researchers at Canadian universities must seek approval from research ethics boards (REBs), which comply with criteria articulated by a Tri-Council Policy Statement authored by Canadian federal health agencies. Researchers in the United Kingdom seek approval from research ethics committees (RECs), which are governed by the Central Office for Research Ethics Committees. Australia's human research ethics Committees (HRECs) and New Zealand's institutional ethics committees (IECs) are likewise answerable to federal agencies.

Common Critiques of Ethics Review Boards

Despite their laudable intent, ethics review boards have faced scrutiny on institutional, logistical, and philosophical grounds. At the institutional level, critics suggest that such boards may act as filters that favor certain types of research. One study indicates that "politically sensitive" proposals are more likely to be rejected because of the potential impact of research findings (Greenberg et al., 2003, p. 316). By the same token, research that appears to support ongoing policy initiatives at the federal level – such as the Rimm pornography study described below – might secure approval more easily. Either way, it is clear that federal regulations can exert undue influence on research agendas.

More broadly, scholars from fields like media studies, sociology, and anthropology argue that social science research is fundamentally different than the biomedical and behavioral research that prompted the development of review boards. Subjection to scrutiny by such boards imposes undue burdens on their work through procedures that even many medical researchers consider confusing, contradictory, and prohibitive. For example, a report from the American Association of University Professors (2006) enumerates incidents of egregious oversight, including one in which an IRB "attempted to deny an MA student her diploma because she did not obtain IRB approval for calling newspaper executives to ask for copies of printed material generally available to the public" and another in which "a linguist seeking to study language development in a preliterate tribe was instructed by the IRB to have the subjects read and sign a consent form before the study could proceed." Since such debates are likely to continue for the foreseeable future, all researchers are well advised to maintain familiarity with the protocols articulated by their home institutions and to understand how these protocols are situated within larger federal and international frameworks.

Media Research: A History of Competing Motives

While avoiding many of the specific biomedical issues that served as an impetus for the formation of ethics review boards, the history of media research is nevertheless

punctuated by its own set of ethical problems. As media research is conducted by commercial and governmental institutions, transnational organizations, communities, and individuals, it is not surprising that questions of motivation and intent have persisted even as methodologies and theoretical paradigms have shifted.

Some of the earliest media research programs were spearheaded by government agencies seeking to manipulate public opinion in support of official policies. In the United States, George Creel's Committee on Public Information launched research programs that aimed at boosting public support for World War I. Working in tandem with the British Propaganda Ministry, these war marketing efforts used fabricated stories to stir the American public from initial pacifism to an aggressive resentment of Germans at home and abroad (Hammer & Kellner, 2009, p. xvi). During World War II, the US War Department conducted experiments to assess the effects of American propaganda films on soldiers. Similar programs continued at major research institutions such as Columbia University, MIT, and Yale (Mody, 2006). Programs such as Yale's Program of Research on Communication and Attitude Change (1946–1961) attempted to understand how opinions and attitudes could be manipulated. Of course, Creel and others defended such efforts as historically justified and appropriately executed. Today, however, many scholars take a dim view of these programs, positioning them as antithetical to the goals of critical media research. Much of today's media scholarship is aimed not at bolstering governmental control of public opinion, but at insuring that emerging technologies and new forms of journalism strengthen the public's influence over governments and corporations.

Ethical issues arise even in projects that aim to empower rather than to manipulate, and where researchers and subjects share mutual goals. Through the United Nations Educational, Scientific and Cultural Organization (UNESCO), for example, media scholars attempted to leverage research on behalf of political and economic development in Africa, the Middle East, and India. Beginning in the 1970s, the Kheda Communication Project in India attempted to use mass media to draw attention to unfair agricultural labor practices. While the prize-winning project garnered praise from some scholars, it often yielded troubling results. The program emboldened workers to strike by publicizing their plight. However, their appearance on local media also revealed their identity to farm owners, who then hired paramilitary gangs to burn down the homes of striking workers (Mody, 2006, p. 882). As discussed below with regard to recent participatory research on community radio in Ghana, the possibility that well-intentioned research may put communities in harm's way persists even when such projects are well executed.

Ironically, even media research specifically aimed at understanding and curbing social problems like violence may produce unintended results. Media effects research traces its history to the Payne Fund Studies (1929–1932), which used experiments and questionnaires to study the effects of movies on children's attitudes and behavior. The studies played a key role in justifying the so-called Hays Code in American filmmaking, which were intended to elevate moral discourse by prohibiting inappropriate content. Having led the charge to impose such codes, many religious

groups came to regret their efforts when, for example, the prize-winning 1948 Italian film *The Bicycle Thief* was denied a Production Code Seal because it contained a scene involving urination and another in a bordello (Moore, 1994, p. 230). Ironically, the codes had only succeeded in limiting viewers' exposure to edifying works of art.

Though widely criticized in popular newspapers, the Payne Fund Studies established a "legacy of fear" about the effects of mass media that has had a lasting impact. The Power Rangers study (Boyatzis, Mattillo, & Nesbitt, 1995), which assessed the influence of the popular children's show on aggressive behavior in children, appeared to support the Payne Fund Study results. Other research suggests that media violence can increase fear in children, desensitize children and adults to real-world violence, and lead to a distorted perception of the amount of violence in the world at large (MediaSmarts, n.d.).

The "powerful effects" model of the Payne Fund Studies was succeeded by a "minimal effects" model and, more recently, a "mixed effects" model indicating a highly complex relationship between media and specific behavior. Indeed, the ethical limitations inherent in media violence studies suggest that such research will tend to yield results requiring nuanced interpretation. Since it would clearly be unethical to manipulate research subjects into committing violent crimes, most media violence research is limited to correlational studies (e.g., comparing media use to self-reported violence or arrest records) or studies that focus on "aggression" rather than violence *per se*. The upshot of these limitations is that "if you are curious whether media violence contributes to violent crime, the simple answer to that is we really don't know" (Ferguson, 2010, p. 39).

But media violence research faces obstacles to nuanced interpretation from the often conflicting motivations of advocacy groups who may aim to support specific legislative initiatives and commercial news organizations, where the "legacy of fear" about media effects creates a potential draw for audiences. These competing motives introduce the possibility that politicians, activists, journalists, and researchers themselves may misrepresent research data. For example, Ferguson (2010) criticizes the American Academy of Pediatrics (AAP) for overstating the number of studies linking media violence and aggression and promoting research that suggests teens are prone to "Facebook depression." In the latter case, critics suggest that the AAP has drawn conclusions that the researchers themselves do not support. By the same token, scholars who support certain legislative initiatives might knowingly craft statements to be issued by advocacy organizations (Ferguson, 2007), or feel compelled to oversimplify results in a way that conforms to the soundbite logic of commercial news. Well-meaning journalists face the problem of presenting complicated research results in a way that is accessible to nonacademic audiences. Meanwhile, content producers at advertising-driven websites – where click rates often override concerns about accuracy – are likely to convert nuanced findings into attention-grabbing headlines.

The financial motives that drive marketing and advertising research raise a related set of concerns. Much advertising research is intended to strengthen campaigns that target children (Wimmer & Dominick, 2011, p. 384). Marketers suggest that children

as young as six months old can recognize corporate logos and can therefore form brand loyalties before they reach two years of age (Barber, 2007, p. 29). Is it ethical to target children before they have the cognitive capability to understand they are being marketed to? Some scholars have advocated against research intended to support such marketing campaigns. In 1999 one group of psychologists called upon the American Psychological Association to “restrict the use of psychological research designed to help sell toys, snack foods, video games, and other products to kids” (Wimmer & Dominick, 2011, p. 384). In the United States, concerns about online marketing to children have resulted in federal legislation such as the Children’s Online Privacy Protection Act (COPPA), enacted in 2000, which requires advertisers and marketers to secure parental consent before collecting data from children under 13.

Other critics suggest that, even when advertising research is aimed at adults, its financial motives are ideologically at odds with the goal of fostering a media environment that serves the public interest. For example, Jeff Chester (2007) argues that reports issued in the early 2000s by the United States Federal Communications Commission, which supported the deregulation of the telecommunications industry, were fundamentally biased by the researcher’s background in professional advertising.

Given that researchers hold different ideological views about the nature and purpose of governments, markets, and other institutions, it is not surprising that they should hold conflicting views about what constitutes ethical media research. Furthermore, even when they hold motivations and goals in common with their subjects, researchers may fail to anticipate certain consequences of their work. Of course, these are the types of issues that ethics review boards are meant to adjudicate. They do so partly by exercising discretion over whether a project can begin in the first place – for example, by considering potential conflicts of interest – and partly by issuing protocols for how specific methods should be implemented. We turn to the latter concerns about conduct and procedures in the next section.

Basic Protocols in Media Research

Assume that you have considered the broad ethical issues outlined above, and have embarked on a media research project involving a conventional methodology such as a survey, questionnaire, experiment, or field observation. What are some of the basic protocols and principles you will need to observe to conduct your research ethically? As noted in the brief history of research ethics above, the concept of informed consent is central to most research projects across the natural and social sciences. Related concepts include debriefing, anonymity, and privacy. Surveys indicate that the majority of researchers employ basic measures to insure informed consent and privacy, although some procedures are used more consistently than others (Greenberg et al., 2003, p. 303).

What does it mean for a research subject to grant his or her informed consent? At minimum, subjects must: be able to make a rational and “mature” decision; know what is going to happen; understand any potential effects; and be free from coercion or pressure (Greenberg et al., 2003, p. 304). Given the first concern, research involving children presents unique challenges (Davies & Mosdell, 2006, pp. 114–115). Researchers should not directly initiate contact with children, but should consult parents first. Even when parents grant permission, children should always have the option to withdraw from a study. Parents are often more willing to allow their children to participate in research projects, while children are more hesitant. Parents should not be allowed to coerce or overrule a child’s wishes. When studying children in a school setting, permission from school authorities and possibly local police may be necessary. Attention to local laws is crucial even if the research involves no direct contact with children, such as videotaping from a distance. One undergraduate student learned these rules the hard way: when he attempted to film children leaving their school for a class on visual anthropology, the local police arrived and stopped the project!

The issue of coercion is present even in more mundane situations. Many graduate students and faculty, for example, will conduct research where undergraduates serve as subjects. Students may feel pressured to participate in research projects for fear of getting a bad grade (Greenberg et al., 2003). When conducting such research, it is important that students know they are free to decline participation without negative consequences.

In order for consent to qualify as “informed,” subjects should be made aware of basic information about the research. Ideally, in addition to knowing that participation is voluntary subjects should also know: (1) who is funding or sponsoring the research; (2) what is being studied, and why; and (3) how long the questionnaire, interview, or experiment will be. Of course, providing too much information about a project can affect the validity of the findings. In some cases, if subjects are informed about what the project is studying, the effects being measured can disappear altogether. Also, if too many people opt out of a study, low participation can bias the sample. These concerns should, of course, be kept in mind. By providing sufficient information about the project without revealing too much, researchers can, however, fulfill the basic requirements for informed consent with relative ease. But if written consent is ideal, it is not always necessary or practical – especially in phone interviews or research requiring subject anonymity.

A controversial alternative to informed consent involves the use of deception followed by debriefing. While no data about how often deception is used in media research is available, deception is frequently used in other fields. In fact, one study found that half of the published social psychology research articles from 1969 to 1979 used deception (Greenberg et al., 2003, p. 306). Though its use has declined in recent decades, deception is still common in much academic research – especially in social psychological studies where disclosure of the research question may impact the validity of results (Wimmer & Dominick, 2011, p. 74).

If a researcher determines that the potential benefits of deception outweigh the risks, the research procedure should be followed by a debriefing in which he or she relates important information that had initially been withheld for the sake of securing more accurate data. This practice is especially important in any situation where “subjects’ perceptions or feelings about themselves or others may have been altered by participation in a study” (Greenberg et al., 2003, p. 308). For example, in Zillman and Bryant’s (1983) study on pornography, subjects who received “massive exposure” to pornography recommended lighter sentences for convicted rapists. In such cases, researchers have an obligation “to attempt to return their subjects to their pre-participation state” (Greenberg et al., 2003, p. 308). Effective debriefing can do more than remove negative effects of the research, in some cases promoting more pro-social or antidiscriminatory behavior. Yet some scholars argue that such methods institutionalize deception, which not only increases cynicism about academic research but breaches basic ethical principles by treating subjects as a means to an end (Greenberg et al., 2003).

The Challenge of Online Environments

As Buchanan (2013) notes, Internet research exists on a continuum that includes studies posing no risks to human subjects and those posing serious danger for subjects whose identity is exposed. Hasinoff’s (2012) research on adolescents’ online sexual behavior, especially “sexting,” exemplifies the former category. The topic is clearly fraught with issues of privacy and consent. In the United States, police have arrested teens and adults for a range of sexting behaviors, including consensual exchanges between teens (Wolak, Finkelhor, & Mitchell, 2012). Research on sexting is limited by its very nature, as analyzing primary materials from private sexual exchanges between adolescents (whether images or text messages) would breach basic ethical standards and violate a range of local, state, and federal laws. In fact, one well-respected assistant high school principal was charged with possession of child pornography and other crimes after investigating rumors of sexting between students (Zetter, 2009). Hasinoff approaches these issues by analyzing public debates and legal discourse about sexting, concluding that such discourse largely overlooks the issue of consent between teens and fails to recognize what she calls a “right to sext” (Hasinoff, 2012, p. 159). While some scholars may disagree with her conclusions, her methodological approach is clearly sound since her analysis of court proceedings and news coverage poses no risk to subjects.

In contrast, one of the most egregious examples of privacy violation and deception in online research occurred in the mid-1990s, just as Internet use was becoming more common. The study is cited by Internet ethics experts as an exemplary case of ethical breaches in online research (Buchanan, 2013, p. 88). Originally published in the *Georgetown Law Journal*, the study was conducted by Marty Rimm (1995), then

an undergraduate student at Carnegie Mellon University (CMU), with the help of a research team. In summary, Rimm and his team conducted an analysis of the text descriptions of pornographic files posted to various adult bulletin board systems (BBSs) in the United States, along with user data obtained from system operators (“sysops”) and private files on the CMU computer system (Thomas, 1996). The study received news coverage in ABC’s *Nightline* television show, was featured in a *Time* magazine cover story, and was cited in Congressional hearings in support of the Communications Decency Act of 1996.

Yet the Rimm study contains serious ethical violations. It capitalizes on the simple fact that the Internet creates new opportunities for researchers to study marginalized or controversial groups: members of racist or other hate groups, victims or survivors of abuse or disease, or – in this case – consumers of legal and illegal pornographic materials. But the researchers used deceptive means to secure data that was not public, without any processes for securing consent. The research team essentially deceived BBS sysops into providing user data from nonpublic forums and then made broad inferences from these data, suggesting that some may be guilty of pedophilia (Thomas, 1996). In this way the authors engaged in a “public stigmatizing” of their own subjects – in violation of the basic principles of justice and “respect for persons” (Thomas, 1996, p. 193). Pitched with ongoing policy initiatives in mind, the project’s grant proposal highlighted the research’s potential usefulness in prosecuting producers and consumers of pornography – the very subjects of the study (Thomas, 1996). The fact that the study received high-level media and political attention before these issues were raised underscores the concerns outlined above with regard to how motivation and intent may cloud ethical reasoning.

At the time, the Rimm study was unique not only for its ethical lapses but also for its focus on unconventional sources of data. Much early Internet research consisted instead of the migration of conventional methods, like surveys, to digital environments. In the early 2000s, surveys conducted by email and web pages were the most common kind of online research (Greenberg et al., 2003, p. 306). While these new platforms generate opportunities for researchers, they also present challenges with regard to the protection of anonymity. When complete anonymity is not possible in offline environments, such as in face-to-face or phone interviews, confidentiality is usually sufficient – researchers might know who the subjects are, but they can insure that personal information will not be disclosed to others. When data is obtained through digital networks and stored in digital form, however, disclosure is harder to prevent. Email presents serious problems, although researchers can use “anonymizer” software tools to hide personal information about research subjects (Greenberg et al., 2003, p. 313). Web pages are better than email, but information can still be compromised by hackers and the presence of data “cookies” stored by browser software. Data encryption techniques can help to alleviate these concerns. The use of deception with subsequent debriefing is complicated by the ease with which potential subjects can communicate and share information with each other. Deception is more easily exposed online, and more likely if an online community considers the project

in question to be intrusive. The first person to take a survey could reveal the deception to all other potential subjects, and this could in turn lead to retaliation (Greenberg et al., 2003, pp. 310–311).

Research involving participant observation in newsgroups, chatrooms, and listservs presents more complex challenges. Even when research is limited to the observation and analysis of online conversations, issues of ownership, informed consent, privacy, and disclosure persist. Many scholars argue that it is unnecessary to secure informed consent from subjects whose messages are publicly available, since posting in a publicly accessible forum suggests implicit consent to having others access, analyze, and even publish messages elsewhere (Wimmer & Dominick, 2011). This assumption informs the basic protocols of some ethics review boards. In the United States, for example, the analysis of text from Internet blogs does not require IRB approval as long as the researcher does not interview the blog authors or conduct a survey among blog participants (Buchanan, 2013). At the most basic level, this assumption is complicated by the fact that many bloggers exercise some form of copyright, sometimes in the form of a Creative Commons (CC) license, which may prohibit the researcher's use of the data outright or place significant conditions on its use. For example, the blog author's CC license may indicate that others may use their posts only if they give credit to the author by name (Buchanan, 2013).

More often, however, the right to privacy in online interactions is assumed rather than asserted explicitly. As Waskul (1996, p. 129) argues, "private interactions" persist in spite of "public accessibility." Though many chatroom or newsgroup posts are technically available to anyone with Internet access, many such forums have such specific target audiences that participants do not expect their messages to be read by anyone who does not share the basic interests, values, or political commitments of the group. Participants may be upset to learn that their conversations are being recorded and analyzed by a researcher (Sveningsson Elm, 2009). As Buchanan (2009, pp. 89–91) observes, "we would not think of walking into a classroom, for instance, without justification or consent, whereas online, we may walk into a newsgroup or online world without such consent, as our presence, our observation, and our research are less obvious." In this sense while participants bear some responsibility for the public nature of their posts, researchers still have a responsibility to disclose their presence, their intentions, and the nature of their research. Despite the latitude granted by some ethics review boards, researchers should bear in mind that even in ostensibly public forums, it is still unethical to disclose information "in ways in which that person has not consented" (Sharf, 1999, p. 253).

These concerns are especially salient in research with online communities that focus on sensitive topics such as health issues, drug use, or gambling. As Krotoski (2010, p. 3) points out, many such virtual communities exhibit a delicate social ecology that may easily be damaged by any type of research, however well intentioned. Participants may leave in protest at any perceived violation of members' privacy or of the integrity of the social space itself. As Sharf (1999) notes in her account of her research on a breast cancer listserv, securing informed consent in such

communities may be difficult but often yields additional benefits. Sharf spent several weeks contacting participants and securing consent for the use of their messages. Many were willing to provide additional information and clarifications, and a few even provided feedback on Sharf's manuscript drafts. More recent exemplary case studies of ethical conduct in online research – including examination of health-related online communities, personal blogs, online gaming spaces, and Internet gambling – are examined in detail in sources such as the *International Journal of Internet Research Ethics* (Krotoski, 2010).

As people spend more time interacting with social media, search engines, and mobile devices, online behavior also generates unprecedented opportunities for commercial organizations to conduct marketing and advertising research. Issues of privacy and informed consent are the subject of ongoing debate. As Vaidhyanathan (2011, p. 97) notes, "every incentive in a market economy pushes firms to collect more and better data on us." Public comments from high-profile corporate leaders have done little to quell these concerns. Facebook's Mark Zuckerberg famously mused that the social norm of privacy has "evolved over time." Sun Microsystems' Scott McNealy quipped bluntly, "You have zero privacy anyway. Get over it," and Google's Eric Schmidt suggested that "If you have something that you don't want anyone to know, maybe you shouldn't be doing it in the first place" (Popkin, 2010).

Online data does raise difficult questions. Are IP addresses personal data? European Union laws suggest they are, but companies like Google and Yahoo object to these arguments (Buchanan, 2013). What kinds of data can be released? In 2006 AOL released a data set of users' searches, claiming they were anonymous, but the *New York Times* was able to cross-check with other public data and identify users (Buchanan, 2013). Facebook has faced user and consumer rights criticism for similar data releases. What inferences can we draw from users' online activities? Reports suggest that insurance companies have denied coverage, and banks have lowered credit limits, based on speculative inferences drawn from users' online behavior, including their searches (Andrews, 2012).

Many kinds of personal data such as legal records and credit information are available online and are technically "public," but are generally untouched by search engines like Google (Werbin, 2012). Is it acceptable for data aggregation companies to use "robots" to find and compile this data with the intent of selling it to advertisers or employers? In 2012 the US Federal Trade Commission issued an \$800,000 fine to the data collection company Spokeo for failing to comply with federal consumer protection regulations. In fact, US companies are not immune from governmental action from abroad. For example, the changes that Google has made to its privacy policies in recent years have mostly been prompted by European policy officials (Vaidhyanathan, 2011).

The related issue of informed consent is likewise complicated in online environments. While Internet browsers and search engines like Google allow users to opt out of personalization features that rely on data collection, such applications exhibit a "choice architecture" that can make it difficult to understand and change default

settings, thereby nudging users toward greater disclosure (Vaidhyanathan, 2011, pp. 88–89). Even if user choices meet basic standards of informed consent, such decisions are made in changing circumstances – data that is currently private may become public in the future, as when Google purchased Usenet archives and enabled users to search them years after the posts had been submitted (Sveningsson Elm, 2009). In response to these concerns and others, the Internet Rights and Principles Dynamic Coalition (IRP), an international group composed mainly of scholars and activists, drafted a Charter of Human Rights and Principles for the Internet that includes specific language regarding privacy and data protection (IRP, 2011).

Research Ethics 2.0? Review Boards Confront the Challenge of Digital Media

While scholars welcome the efforts of groups like the IPR in translating established human rights principles to the digital environment, institutional review boards have faced challenges in applying such principles in the context of academic research. Formal codes of conduct may be problematic because they can become outdated very quickly. Critics suggest that review board members who are unfamiliar with new technologies may not be equipped to evaluate online research proposals. Often, reviewers attempt to fit Internet behavior and communication into the mold of offline communication, sometimes with results that seem irrational. Jones (2004) notes that in one case a student was asked to provide “a signed informed consent form for each subject in an online chat room,” despite the anonymity of the participants, and was further instructed that since the participants were using multiple identities, she would have to provide a separate consent form for each (p. 181).

The prospect of drafting new rules as new online environments emerge is daunting. The Internet is not a singular space but rather a conglomeration of multiple spaces and formats including email, chatrooms, Usenet groups, instant messages, and multi-user dimensions (MUDs). Even if rules could be established for each unique online space, the question remains as to whether rule-based approaches are always appropriate. Thomas (2004) argues that an emphasis on rules and precepts reduces our sensitivity to context. Ironically, overemphasis on rules can “subvert ethical awareness” (Thomas, 2004, p. 196) by relieving us of contextual ethical thinking and by pushing researchers into a position of wishing or needing to rebel against overly restrictive constraints. Ultimately, Thomas suggests, “no set of rules, formal or otherwise, can provide unambiguous answers to complex ethical questions that often arise” (1996, p. 197). Of course, this criticism applies to most research covered by institutional review. By their very nature, ethics review boards tend to take a legalistic, rule-based approach to research governance (Buchanan, 2013), and this aspect of institutional review is unlikely to change.

Rather than shoehorning offline rules into online environments or rejecting rule-based governance altogether, Buchanan (2013) suggests that the responsiveness and

relevance of governing structures may be improved by incorporating some of the emergent dynamics of online environments. In contrast to the top-down nature of most institutional governance, Internet communication can often be more relationship-based, with social networks emerging “from the ground up” (Buchanan, 2013, pp. 102–103). By learning from the emergent dynamics of networked communication, review boards may envision an “open-source ethics” approach that is more participatory and pluralistic than traditional governance models. As Buchanan argues, “research itself cannot be transformative if the models that govern it remain static” (p. 103).

International groups such as the Association of Internet Researchers (AoIR) have enabled this type of open-source approach by establishing Internet research as a distinct domain and by articulating ethical frameworks for its conduct (Ess & Association of Internet Researchers, 2002; Markham & Buchanan, 2012). While researchers may still have trouble applying such well-informed guidelines in the complex and rapidly changing context of online environments (Sveningsson Elm, 2009), Buchanan (2009, p. 92) suggests that ongoing discussion and refinements are healthy and that over time, “alternative models of protections will evolve” to address the unique issues of privacy and consent in online spaces. In this sense, what Buchanan (2013, p. 83) calls “Research Ethics 2.0” is a welcome development, involving not simply changes in rules of conduct but also adjustments in the very structure of institutional governance for a wide range of fields.

The Challenge of Participatory and Activist Research

As Buchanan (2013) notes, in many ways the ground-up communication models afforded by digital environments resonate with feminist, communitarian, and activist-oriented research paradigms. Indeed, just as new media technologies complicate conventional ethics protocols, participatory and activist methods present similar challenges by re-envisioning research not as “the transmission of specialized data” but as “a catalyst for critical consciousness” (Christians, 2007, p. 59).

Ethnography has long positioned itself as distinct from the conventional methods that review board protocols are designed to address. While sometimes falling under the discretion of institutional review, much ethnographic and other qualitative research qualifies for expedited review or is exempt. Even if a project is exempt from review, however, professional codes in fields like anthropology stress that issues such as informed consent must not be overlooked by researchers.

Some scholars question whether concerns about informed consent, privacy, and deception always pertain in the context of methods like autoethnography, ethnodrama, and participatory action research, where the traditional researcher/subject distinction is replaced by a voluntary relationship of “reciprocity between two subjects” (Christians, 2007, p. 58). Echoing Denzin (2003, p. 60), Christians argues that

qualitative research exhibiting this type of reciprocity “ought to be excluded from IRB oversight” in the same manner that the Oral History Association (OHA) secured exemption from IRB overview in 2003. Significant ethical issues persist, however, and OHA has implemented its own research guidelines despite its exemption from IRB review. Ethical risks persist in post-ethnographic work as well, and, in fact, the political nature of much critical qualitative work – especially its engagement with marginalized groups and its vision of a “social ethics of resistance” (Christians, 2007, p. 56) – suggest that such research may involve significant risks for researchers and their communities of affiliation.

The perception of mutual interest and reciprocity is fraught with political and cultural tensions. Which set of persons, organizations, or institutional structures are best qualified to assess the reciprocity of research–subject relationships, and which protocols should be observed to maintain it during the project? Even if the voluntary and reciprocal nature of a project can be insured, the vulnerable nature of many marginal communities surely means that issues of consent, privacy, and confidentiality cannot be overlooked.

In their account of a successful, grant-funded participatory action project in Ghana, researchers from the Institute of Development Studies (IDS) demonstrate how such issues can be addressed effectively in projects built on a firm foundation of trusting relationships and clarity of purpose (Harvey, Burns, & Oswald, 2012). Using the methods of participatory action research, IDS worked closely with the Ghana Community Radio Network (GCRN) in an initiative called Climate Airwaves, the purpose of which was to “create a space to share knowledge on the causes, impacts, and responses to climate change, and to advocate for social and political change in response to these issues” (Harvey et al., 2012, p. 103). GCRN had worked with IDS previously, and suggested action research as the preferred method for the project (Harvey et al., 2012).

In collaboration with the local community, the project leaders decided to focus on the issues of coastal erosion and falling crop yields. Project leaders incorporated station broadcasters, community members, and local authorities into the investigation and analysis of these ecological concerns, producing a “holistic analysis attentive to the role of power in shaping people’s vulnerability or resilience to climactic impacts” (Harvey et al., 2012, p. 112). Without this holistic approach, the researchers argue, analysis of the erosion and crop yield problems would have focused on solutions (such as a sea wall defense) that would have neglected the needs of local communities.

During the process of investigation, however, the researchers note that GCRN faced sensitive decisions about how to protect the anonymity of community members in its broadcasts, especially when touching on “politically charged issues” (Harvey et al., 2012, p. 109). At the same time, since GCRN stations strive to remain neutral with regard to party politics, the researchers had to insure that their inquiry process did not make stations appear partisan. Ultimately, the project teams navigated these issues effectively, and they not only yielded proposals that highlighted the needs of

local communities but sparked new dialogue between community members and traditional authorities where conflict and secrecy had previously prevailed (Harvey et al., 2012). The research yielded valuable insights for media scholars, demonstrating first that radio can bolster the aims of action research by generating new lines of inquiry based on community feedback, and second that action research can help broadcasters to envision new models for long-term investigative projects that more directly serve the needs of local communities.

IDS researchers devoted significant attention to ethical concerns before executing the Ghana project. While IDS has its own ethics panel, it is typically reserved for larger-scale projects. However, as a requirement for securing funding the researchers conducted extensive discussions regarding ethical issues with Carleton University, in conjunction with the International Development Research Centre (IDRC). Moreover, dialogue regarding ethical issues unfolded with GCRN and the World Association of International Radio Broadcasters (AMARC) during the development of the research proposal, including concerns about engagement with broadcasters and community entry (B. Harvey, personal communication, January 17, 2013).

The IDS community radio project suggests that the goal of “transformative social change” may, in fact, be pursued effectively within the context of grant-funded research that is typically subject to rigorous review (Harvey et al., 2012, p. 101). Furthermore, it demonstrates that issues of anonymity and potential harm to local activists and media organizations persist even when the relationship between researchers and local communities is one of mutual interest established over time. As with Internet research, the ethical issues in emergent research models are often unique and many institutional boards have yet to fully appreciate the ethical concerns raised by post-ethnographic studies. Rather than pursuing a “policy of strict territorialism” (Christians, 2007, p. 60), however, institutional boards may benefit from sustained dialogue with organizations that are well versed in their proper execution. As Buchanan (2009) indicates with regard to Internet research ethics, alternative models of protection may evolve over time.

Certain critical ethnographic projects may ultimately be exempt from review. Even in such cases, however, researchers are well advised to follow the guidelines provided in professional codes of ethics such as those articulated by the American Anthropological Association. Additional case studies and guidance for navigating the ethical terrain of critical ethnographic studies is available in sources such as D. Soyini Madison’s *Critical Ethnography: Methods, Ethics, and Performance* (2011).

Accepting the Challenge of Media Research Ethics

As the cases in this chapter demonstrate, all forms of media research involve significant ethical considerations, from the mundane “Is my project exempt from institutional review?” to the philosophical “What is the social benefit of my research?”

These questions are part of an ongoing debate that reaches beyond media research to the broad historical, cultural, and political contexts in which the field arose. While all scholars will encounter some portion of this spectrum of issues, many can proceed in their chosen line of inquiry without venturing too deeply into the thickets of institutional protocols, professional codes, emerging technologies, funding, or post-ethnographic critique. Yet it behooves all media scholars to achieve some level of literacy in all of these areas. Researchers are accountable for the social impact of their work and, as suggested at the outset of this chapter, questions of motivation and intent are among the first that researchers should consider. The persons and communities studied by researchers should never be a means to an end, whether personal or professional, but an end in themselves. The goal of research is the enhancement of human flourishing.

As such, the theoretical and philosophical frameworks that inform one's work should not be taken for granted as settled matters but as contested sites requiring self-reflection and continued engagement with a diverse community of scholars. For this reason it is beneficial for students and faculty to forge personal and professional relationships that cross disciplinary and ideological boundaries. At the same time, one should not assume that any particular line of research will remain untouched by the "mission creep" of ethics review boards and other institutional structures. It is important to at least remain aware of, if not become actively involved in, debates about the overall reach of, as well as the specific rules outlined by, professional organizations. Just as technological forms and protocols can become locked in over time, so too can the guiding philosophies and logistical protocols of academic organizations. Change becomes more difficult to enact once critical junctures have passed. As Buchanan (2013, p. 103) suggests, "researchers should not turn away from their ethics boards; instead, they should work in tandem to forge the next generation of research ethics, one that still embraces core principles while creating new opportunities for important research endeavors." Doing so may indeed be difficult, as speaking truth is a matter of conviction, commitment, and often courage. To remain aware and engaged in this manner, and to encourage others to do so as well, is to accept the challenge of media research ethics.

Doing Survey Research in Media Studies

Suman Mishra

ABSTRACT

Survey research is a widely used methodology for collecting quantitative data and is particularly useful for conducting research in communication and media studies. This essay provides an overview of survey methodology, its historical background, and its uses in communication and media studies. It explains some of the basic concepts in survey design such as sample, sampling procedures, questionnaire design, and modes of distribution of questionnaires. It also provides a guideline for conducting survey research and discusses some of the unique challenges faced by survey researchers both within a single country and internationally when conducting cross-cultural survey research. The chapter concludes with a discussion of ethical issues in survey research.

Information is a valuable commodity that is of great importance to governments, businesses, and institutions. Thus information is constantly being gathered using various techniques, tools, and methods all over the world. Anybody who uses the Internet today has seen or filled out a survey asking for their opinions on topics ranging from the trivial (celebrity dress and cat videos) to more serious social, political, and economic issues. Most people today have also seen the use of survey techniques to measure television viewing or public opinion on political candidates and

issues, or in market research to understand public attitudes toward products, brands, or advertising campaigns. However, most of the surveys we encounter in our everyday lives are not conducted in a scientific manner, and thus their results are skewed, biased, and not generalizable to the population that is being studied.

A scientific survey methodology is a *quantitative research* method that uses a well-designed *questionnaire* to collect data from a *representative sample* in order to *generalize* to a *population*. Media researchers who want to use survey methodology for their study must carefully examine the issues surrounding *survey questions and instrument design, sampling, data collection*, and *analysis* in order to reduce error and to increase the precision of their findings. In addition, media researchers who want to conduct global or cross-cultural research to compare data across countries must take into account differences in language and culture that affect survey design and responses.

This chapter covers the history of survey methodology, focusing on its use in media and media studies, discusses when to use survey methodology, provides procedures for conducting a survey, discusses some of the unique challenges in conducting survey research in general and in conducting cross-cultural survey research in particular, and concludes with a discussion of the ethical issues in survey research.

History and Uses of Survey Methodology in Media Studies

Historically, the need for surveys in the United States began with article 1, section 2 of the US Constitution (Converse 2009; Groves 2011), which says:

Representation and direct Taxes shall be apportioned among the several States which may be included within this Union, according to their respective Numbers . . . The actual Enumeration shall be made within three Years after the first Meeting of the Congress of the United States, and within every subsequent Term of ten Years, in such Manner as they shall by Law direct.

This requirement of a decennial census was meant to aid proportional representation in the House of Representatives as well as in the appropriation of taxes. A *census*, which involves gathering information from every individual in the population, has been a great source of information for making decisions in the governmental realm. Today, however, individuals and institutions use census data for purposes such as the distribution of federal funds; planning for hospitals, schools, transportation, and other services; the understanding of labor supply, migration, and urbanization; the delivery of goods and services; the planning of political campaigns; the setting up of businesses and retail outlets; and the delivery of catalogs and direct mail. A census, although it may be desirable to study populations, is difficult to administer and

requires massive resources to conduct. Most people cannot undertake a census; thus they study smaller groups or samples to fulfill the research need.

Media's use of surveys began in the nineteenth century when newspapers wanted to find out the voting preference of their local audience (Martin, 1984). The early polls were mostly local, less scientific by today's standards, and dealt with voters' choice in an election rather than with public opinion on issues. Newspapers such as the Harrisburg *Pennsylvanian* and the Raleigh *Star* conducted public polls before the presidential elections, and other newspapers and magazines such as the *Boston Globe*, *Farm Journal*, and the *Literary Digest* followed suit (Martin, 1984). Data were often gathered using questionnaires that were published in newspapers and magazines for readers to fill out and mail in, or interviewers were sent to people's homes. These kinds of surveys and polls reflected the views of the subscribers of those magazines and newspapers, not quite those of the general public. Nevertheless, journalists found the polls useful as they added credibility and weight to their news stories (Groves, 2011).

The modern survey methodology that uses a small subset of the population, the *sample*, to represent the population was developed in the twentieth century. Groves (2011) describes three distinct eras of development of modern survey research. In the first era (1930–1960), the basic components of survey design and statistical analysis was invented. The second era (1960–1990) saw the wide implementation of survey methodology in areas such as social science, political science, consumer research, and market research. Researchers from different fields often used survey methodology to gather information for the US federal government and to make business decisions. In the third era (1990 to the present), Internet technologies began to be used to gather data quickly and easily. Even though mobile and web technologies make it easy to conduct surveys, researchers are finding that people's participation in survey research is declining, which poses challenges for survey researchers (Groves, 2011).

Empirical survey research in media studies began in the early part of the twentieth century. The credit for growth and development of modern surveys is given to several individuals. Among them are Paul Lazarsfeld and George Gallup. Walter Lippman's seminal work *Public Opinion* (1922) laid the groundwork for media studies and media research. His writings focused on media's influence on public perception and public policy. Thus began a series of research to understand media's influence on the public. One of the prominent social scientists who studied mass communications using survey methodology was Paul Lazarsfeld. Lazarsfeld established the Office of Radio Research at Princeton University to study the importance of radio, the new medium of the time, in the lives of listeners. His work focused on understanding the voting behavior of the public and the persuasive appeal of mass media. Lazarsfeld's works, *The People's Choice* (Lazarsfeld, Berelson, & Gaudet, 1948) and *Personal Influence* (Katz & Lazarsfeld, 1955) broke new ground in mass communication research in the 1940s and 1950s. The two-step flow theory, the role of the opinion leaders in mediating the influence of media, and media's role in creating a

passive audience – described as “narcotizing dysfunction” – are just a few of his paradigm shifting contributions to media research. Lazarsfeld not only contributed to the development of media theories; he also developed panel studies and contextual analysis and perfected the survey methodology. He trained many researchers at his Bureau of Applied Social Research in Columbia University and inspired the establishment of many institutional research centers within the United States and abroad (Merton, 1979). Institutional research centers such as the NORC at the University of Chicago and the Survey Research Center at the University of Michigan today conduct local and national surveys on a regular basis. Converse (2009) notes that there are more than 2,000 nonprofit research centers and many more for-profit research firms.

The other person who helped develop survey methodology was George Gallup. Gallup rose to national prominence in 1936 when he correctly predicted Franklin Roosevelt’s win over Alfred Landon for the US presidency, contradicting the predictions made by *Literary Digest*, the leading poll of that time. This event gave credibility to scientific polling methods, which did not just rely on large numbers of respondents but used a representative sample (Gallup, n.d.; Gallup & Rae, 1940). Gallup applied survey research methodology in many areas of media research, including newspaper readership, radio listenership, print and television ad effectiveness. He also tested the appeal of Hollywood story ideas among the public (Gallup, n.d.).

Over a period of time, surveys became one of the most popular research methodologies. These were used in political polling; media audience studies; estimating audience size for newspapers, magazines, television, and so on; testing advertising effectiveness, brand awareness, market share; and other forms of consumer research. Survey research methodology is also popular among media scholars in academia who often study the social effects of media. For example, George Gerbner’s famous studies on the effects of television violence on the public included survey methodology (Gerbner & Gross, 1976; Gerbner, Gross, Morgan, & Signorielli, 1980).

When to Select Survey Methodology

There are many research methodologies available to media researchers. Each method has its strengths and weaknesses. Survey methodology is best suited for studies where the goal is to produce *quantifiable* and *generalizable* results, particularly results that can help in decision making and policy implementation. There are, of course, times when the researcher is not concerned with numerical precision and just wants to get a feel for an issue, idea, or opinion. In these cases too survey methodology can be helpful. Survey methodology can be used for exploration, description, and explanation (Adams, 1989). It can help to demonstrate correlational links between the variables. However, researchers should not rely on survey methodology to prove

causation. Causation can be best demonstrated using experimental research methodology.

Procedure for Conducting a Survey

Survey methodology starts with the research question the researcher wants to answer. It then involves making decisions on study design, the mode of administering the survey, whom to survey, what kind of questions to ask, and how to ask them. While these are important for all studies involving survey methodology, cross-cultural survey studies have an additional layer of complexity. Cross-cultural researchers have to think about issues of *equivalency* for their data to be comparable across the countries or cultures being studied. Thus they have to strive for *sample* equivalence, *linguistic* and *conceptual* equivalence, and *metric* or *instrument* equivalence (Choudhry, 1986; De Mooij, 2010; Douglas & Craig, 1983; Mueller, 2006). These will all be discussed later in the chapter.

Selecting a Study Design

There are two main types of survey study designs, cross-sectional and longitudinal. The purpose of the study determines the study design. Cross-sectional studies are done once to fulfill the information need. *Longitudinal studies* collect data from a sample over a period of time. Longitudinal studies often measure the same sets of variables over a time period and help in noting changes in attitudes, opinions, or behaviors. Even though longitudinal studies tell us the trend or changes that are taking place, they do not tell us why the changes are occurring. Changes in a population occur for various reasons. They can be due to the natural growth of individuals as they move through the life cycle or to a circumstance or major event in their life. *Cross-sectional studies* are more common among media researchers than longitudinal studies because they serve the need for current data and provide a snapshot of a population at a given time. They are also quicker, cheaper, and require fewer resources to carry out. Longitudinal studies are time-consuming and costly to conduct.

There are three basic kinds of longitudinal studies: trend, cohort, and panel studies. *Trend studies* involve studying a population at different times. Smith (1980) did a trend survey from 1946 to 1976 called “America’s most important problem” to understand changes in long-term and short-term public concern. *Cohort studies* involve collecting data over a period of time from the same subgroup of the population (called a cohort). Cohorts are basically people who are linked together in some way, for example a high school graduating class of 2013. Here the researchers don’t have to collect data from the same individuals over a period of time. Instead they can collect data from anyone in the cohort. Rentz, Reynolds, and Stout (1983) studied

a cohort to understand how aging affects the consumption of soft drinks. The Centre for Longitudinal Studies in the United Kingdom often conducts cohort studies. One of their studies is the Millennium Cohort Study (MCS), which involves 19,000 children born in the United Kingdom in 2000–2001, to understand the diverse issues affecting this generation (Centre for Longitudinal Studies, n.d.). *Panel studies* differ from cohort and trend studies in that they involve gathering information over a period of time from the same sample of respondents (called a panel). In cohort and trend studies, different individuals may be surveyed but in panel studies the same individuals are often studied. The University of Michigan has been conducting a panel study since 1968, the longest panel study in the world, called the Panel Study of Income Dynamics (PSID). It involves a study of 18,000 individuals living in 5,000 families. There are shorter panel studies too. Aubrey (2006) conducted a two-year study exploring the effects of sexually objectifying media on self-objectification among a panel of undergraduate students.

Assessing the Mode of Delivering the Questionnaire

Researchers have to think in advance about how to deliver the questionnaire to the respondents. Survey researchers commonly administer surveys in person, also called in-depth interviews (IDIs) or face-to face interviews, by mail, by phone, or over the Internet using emails or websites. The choice of the mode through which to administer surveys depends on several factors such as speed, cost, comfort level of the respondents with the mode, literacy level, sensitive nature of the questions, and whether the researcher wants to incorporate audio, video, or any other graphics in the survey.

Email and web surveys are much faster to administer than mail surveys. Surveys conducted in person are much more expensive than mail, Internet, or phone surveys. If the population from which the researcher wants to collect data is not comfortable using the Internet or does not have access to a computer, this is not a viable option for delivery. Similarly, mail and Internet surveys are not the best options for collecting data from people who are illiterate or less educated. In this case in-person interviews might be necessary. If the research involves asking sensitive questions such as those related to sex or diseases, face-to-face collection of data can make the respondent uncomfortable. In this case mail or Internet surveys might be the best option. Media studies often involve noting reactions to images, audios, and videos. This can limit the options that the researcher has. One can play or show the images on a computer during a face-to face session to note the reaction or administer it over the Internet. Web technologies have made it much easier to incorporate videos and graphics in a survey, which can be sent to the respondents to watch, after which they can answer the related questions. However, if the graphics or videos are of a sensitive or sexual nature, the researcher needs to think in advance where the respondents are likely to

access the survey: at home or in a public area. College students often use college facilities such as libraries or computers in a public area to do their work and might feel embarrassed watching sexual content in a public area. In this case, before the video is played, it is important to warn the audience about the nature of the content. More pros and cons of using a particular option to administer a survey are listed in Table 3.1.

Table 3.1 Advantages and disadvantages of different modes of administering a survey

Face-to-face interviews	Telephone survey
<i>Advantages</i> • Gets a good response rate • Allows interviewers to clarify questions and to probe further for more details • Visuals and audio can be incorporated • Open-ended and lengthy questionnaire possible <i>Disadvantages</i> • Requires training of interviewers • Costly and time-consuming • Interviewer bias is difficult to avoid • Reaching some locations physically might be difficult • Eliciting a response to sensitive questions may be difficult	<i>Advantages</i> • Relatively cheap and fast to conduct • Greater response rate than mail surveys <i>Disadvantages</i> • Cannot reach people without phones or those registered with the “do not call” registry • Requires training of telephone interviewers • No visuals can be incorporated • Open-ended and lengthy questionnaire not possible • People screen calls; this affects response rate
Mail survey	Online/web survey
<i>Advantages</i> • Relatively cheap to conduct • Allows for anonymity • Sensitive questions can be asked • Respondents can answer questions at their own pace • Allows for a wider geographic reach <i>Disadvantages</i> • Takes longer to conduct • Respondents do not always return the questionnaire • Low response rate • Respondents need to be literate	<i>Advantages</i> • Fast, efficient, and less expensive • Allows interactivity and incorporation of audio and video material • Multiple contingency questions can be incorporated without confusing the respondents • Reaches people in a wide geographic area • Can help avoid interviewer bias • Anonymity allows for sensitive questions to be asked <i>Disadvantages</i> • Respondents have to have access to computer and Internet technologies • Respondents need to be literate and comfortable with web technologies • Sampling difficult, as there is no national framework of Internet users • Low response rate

Selecting a Sample

In research it is neither practical nor feasible to collect data from every individual in the population one wishes to study. Thus sampling techniques were developed to select a sample from the population that accurately represents the population. A *population* is an entire group of people a researcher wishes to study. A *sample* is obtained from a list of individuals in a population. Whenever a sample is chosen from the population and not the entire population, there is always a chance that the sample does not accurately represent the population. This is referred to as *sampling error*. Sampling error can be reduced by increasing the sample size and by employing a scientific sampling procedure.

To select a sample from the population involves making decisions about some key issues such as the *sample frame*, the use of *probability or nonprobability sampling procedure*, the actual *sample size*, and the *response rate*. In cross-cultural research, the researcher also has to establish *sample equivalence*, that is, a sample in one country should match the sample in another country. De Mooij (2010) notes that a student sample that is generally considered similar across nations might not be so similar. For example, students in the United States generally live on campus, in Europe they live independently, and in Asia they often live with their parents. In addition, students in nations with a large income disparity often represent the upper strata of the society. Thus student samples across the world might not be similar.

Sample Frame

A sample frame consists of individuals or units from the population from which a sample is selected. A researcher normally does not have direct access to the population, so he or she relies on the sample frame to select a sample. Some of the commonly used sampling frames are: a list of registered voters, employment files, a list of driver's license holders, a telephone directory, a list of students enrolled in a university, and a list of organizations. The quality of the sample frame affects the quality of the sample. A sample frame should be selected based on its comprehensiveness in representing the population, probability of selection, and efficiency with which one can make the selection (Fowler, 2009).

Sampling Procedure

Once the researcher has selected the sample frame, the researcher has to decide how to select individuals or individual units to make up the sample. The two main techniques for drawing individuals for a sample from a sample frame are *probability* and *nonprobability sampling*.

Probability Sampling

Probability sampling procedures are considered more scientific and statistically precise, as they allow the researcher to calculate *sampling error* – the difference between sample characteristics and the population characteristics. In probability sampling each individual or individual unit has an equal chance of being selected. Thus the assumption is that random selection will lead to bias free selection of the sample that better represents the population one is trying to study. *Simple random sampling*, *systematic sampling*, *stratified random sampling*, and *cluster sampling* are common approaches to probability sampling.

Simple random is the basic probability sampling technique that is often described as similar to drawing a sample out of a hat. For example, if a researcher's sampling frame includes a list of 1,000 individuals from which he or she has to draw a sample of 100 individuals, the names of all 1,000 individuals will be first placed in a container for drawing. Then 100 names will be picked at random from the container, which is the sample for the study.

Researchers are also known to use a table of random numbers to generate a simple random sample. For telephone surveys, a simple random sample is often obtained through the process of *random digit dialing* (RDD). There are various ways for obtaining a sample through random digit dialing. The Pew Research Center explains its RDD process for landlines (Pew Research, 2013): "This method uses random generation of the last two digits of telephone numbers selected on the basis of the area code, telephone exchange, and bank number. A bank is defined as 100 contiguous telephone numbers, for example 800-555-1200 to 800-555-1299."

Systematic sampling is similar to simple random sample, but here the researcher first determines who will be included in the sample by calculating a fraction. For example, if the researcher wants a sample size of 100 from a list of 1,000 individuals, he or she first divides 100 by 1,000 to get $1/10$. This fraction suggests that 1 out of every 10 individuals needs to be selected in order to get a sample of 100. This is also known as the *sampling interval*. To determine a starting point for selecting a sample from the 1,000 listed in the sampling frame, the researcher picks any random number that falls within the sampling interval, which in this example is any number between 1 and 10. This is done to insure the selection process is by chance and not based on any judgment or bias. Let's say that the random number chosen is 4. The number 4 then becomes the starting point for sample selection, and every 10th individual on the list after 4 is included in the sample, that is, those listed as number 14, 24, 34, and so on till one obtains a sample size of 100.

Stratified random sampling is best used when one needs to highlight certain subgroups within a population or to maintain a certain proportion of subgroups in a sample. It is used, for example, if the researcher is interested in studying differences in attitude toward obesity between various subgroups of the US population or an advertiser is trying to study various target groups for a product. In these cases it is useful to have representatives from subgroups such as African Americans, Hispanics,

Native Americans, and White Americans in the sample. In order to insure a representative sample, it might be useful to first divide the population into subgroups, or *stratum*, and then randomly select the same proportion of individuals from each stratum that one finds in the population. This insures that the sample represents the racial makeup of the population.

Cluster sampling is best used when a complete list of the population is difficult to construct or when the population naturally lives in clusters, such as college students. Cluster sampling is frequently used for studying public health issues. In cluster sampling the population is usually divided by geographic locations, regions, districts, counties, or postal zip codes, commonly referred to as *clusters*, and clusters are randomly selected for the study rather than individual units.

Nonprobability Sampling

Sometimes the researcher might just want to conduct an exploratory study to get a feel for what people are thinking or how they react to products and packaging. In this case the researcher is not concerned with numerical precision or accurate representation. So he or she would use some form of convenience sampling procedure to select a sample. The advantage of using nonprobability sampling procedures is that it helps to get a sample quickly and cheaply, but the disadvantage is that the sample obtained through this procedure is often skewed in terms of demographics or psychographics. For example, media researchers in academia often use university students as a sample because they have easy access to them, and students are more willing to participate for the extra credits they gain. However, university students do not accurately represent the adult population even though most university students are adults. Similarly, when journalists use websites for their opinion polls and “person on the street” interviews to get a quick feel for an issue, the characteristics of the respondents who participate in the poll most likely do not represent the characteristics of the population. Even though the sample obtained using the nonprobability sampling procedure is not mathematically precise, it is still useful for media research. There are various forms of nonprobability sampling procedures: *purposive*, *convenience*, *haphazard*, *volunteer*, *judgment*, *quota*, and *snowball sampling*.

In *purposive sampling* researchers select respondents based on certain criterion or characteristics, such as purchase behavior, interests, and so on. People who meet the criterion are selected for the study, while others are eliminated. For example, a researcher wanting to know why women buy brand X shampoo might only include those women who have purchased brand X in the past, while other men and women are not selected.

In *convenience or haphazard sampling*, there is no specific criterion for selection. It is based on ease of access to the sample or practical convenience.

These days television hosts and radio stations often ask their viewers to go online to participate in polls or to give their opinions of a topic. Individuals volunteer to be part of the study. This procedure is called *volunteer sampling*. Volunteer sampling technique, even though convenient, has all the flaws of a nonprobability sampling

technique. For example, one does not know who is participating in the study. Wimmer and Dominick (2010) note the unethical behavior of radio stations that respond to the volunteer call of competitive radio stations and intentionally provide fake information to cause them to make wrong decisions.

Judgment or expert sampling involves the subjective judgment of the researcher or an expert in selection of a sample.

In *quota sampling*, nonrandom sampling is done to fulfill a certain quota or limit. For example, if the researcher wants a sample of 100 individuals for a study and knows that the university population is 45 percent male and 55 percent female, he or she might sample until the quota of 45 males and 55 females is met. This is called *proportional quota sampling*. In *nonproportional quota sampling* one is not concerned with the sample proportions matching the population proportion. The goal is to have enough males and females to make up the sample of 100. Quota sampling is in some ways similar to stratified sampling, except that the selection is nonrandom and is based on ease of access.

Snowball sampling involves identifying someone who meets the criteria that the researcher is looking for and then asking him or her to recommend others who also meet the criteria. This technique is useful for studying populations that are not easily accessible, such as homeless individuals, drug dealers, and illegal or undocumented immigrants. Having access to such an individual and gaining his or her trust can help in getting access to others for the study.

Selecting a Sample Size

The most common dilemma for a researcher is to determine the sample size for the study. There is no consensus among researchers on the sample size. The frequent sample size one comes across for a national survey ranges from 1,000 to 1,500 participants, and for a local survey the size is about 500. Fowler (2009) suggests that sample size should be decided on a case-by-case basis, taking into account the margin of error the researcher is willing to tolerate and the level of precision he or she wants. Wimmer and Dominick (2010) list seven factors that determine the sample size: *project type, purpose, and complexity; amount of error tolerated; time and financial constraints; and previous research on the topic area*. There are many books on statistics that contain charts or published tables and formulas that can help media researchers determine the size of the sample for their study (see Comrey & Lee, 1992; Fowler, 2009; Krejcie & Morgan, 1970). In addition, sampling statisticians can also guide media researchers in this area.

Designing a Questionnaire

Designing a questionnaire to collect data from sample respondents is an important part of survey design. The key issues in questionnaire development are *what questions*

to ask and how to ask them, what measurement scales to use, and the appearance of the questionnaire.

The first and foremost issue in writing a good questionnaire is defining the key concepts one wishes to study. We often use the terms “attitudes,” “values,” “beliefs,” “liberal,” “conservative,” “self-esteem,” and so on in our daily lives. However, understanding of the meaning of these terms differs from person to person. Media researchers need to clarify and clearly define these concepts for a common understanding between the researcher and the survey respondent.

Let’s take the example of a researcher trying to study violence in video games. The term “violence” can mean different things to different individuals. For example, it can include physical, mental, verbal, and sexual violence. Even within physical violence, pushing and shoving is not the same as shooting, murder, and rape. Thus a questionnaire eliciting a response on violence in video games might get varied responses based on the individual’s understanding of the concept. It is thus important for a researcher to provide a *conceptual* and an *operational definition* of the concepts he or she is trying to study.

A *conceptual definition* includes identifying and defining key constructs of a concept. For example, what do the concepts “attitude” and “violence” mean? One can use the definitions used by other scholars or, when necessary, come up with a new definition. For example, Gerbner and his colleagues defined violence as “an overt expression of physical force against self or other, compelling action against ones will on pain of being hurt or killed, or actually hurting or killing” (Signorielli, Gross, & Morgan, 1982, p. 163). Similarly, the concept of “attitude” toward advertising can be defined as “a learned predisposition to respond in the consistently favorable or unfavorable manner to advertising in general” (Lutz, 1985, p.53).

When measuring a concept in a cross-cultural media research, the researcher needs also to establish *conceptual equivalency*. For example, the concept of “family” differs in different parts of the world. Family in the United States usually refers to a nuclear family, in which there is a mother, a father, and children, but in many Asian countries “family” may include uncles, aunts, grandparents, and cousins (Mueller, 2010).

An *operational definition* involves creating actual measurements for a concept. For example, the concept of an “attitude” toward an ad can be measured by asking very specific questions, such as whether the ad was good, interesting, informative, appropriate, easy to understand, and objective (Henthorne, Latour, & Natarajan, 1993). When measuring a concept, the researcher should make sure the measurements are reliable and valid. *Reliability* refers to the consistency of the measure. In other words, if the same measure is used multiple times to measure a concept, it should consistently yield the same result, just as a good weighing scale does when measuring the weight of a person. *Validity* refers to the accuracy of the measurement: is the measurement measuring what it is supposed to measure? If a researcher is trying to study attitudes but is measuring behaviors, the measurement is not valid.

When it comes to measurement of variables, it is not always necessary to develop one's own measurement scales. Many researchers find it convenient to use standard measurement scales created by other researchers in the fields of mass communication, sociology, psychology, and market research instead of creating their own scales for measuring concepts. There are many handbooks on measurement scales that media survey researchers can use, for example, *Handbook of Marketing Scales: Multi-Item Measures for Marketing and Consumer Behavior Research*, edited by Bearden, Netemeyer, and Kelly (2011); *Measures of Personality and Social Psychological Attitudes*, edited by Robinson, Shaver, and Wrightsman (1991); and *Communication Research Measures: A Sourcebook*, edited by Rubin, Palmgreen, and Sypher (2009). The advantages of these measurements are that they have been tested for their reliability and validity. However, they may not be suitable for the researcher's particular needs. In that case, the measurements have to be developed or adapted.

Types of Questions

A survey researcher can ask open-ended or closed-ended questions. *Open-ended questions* elicit detailed answers from a respondent. The following questions are examples of open-ended questions:

- Tell me about . . .
- What do you think would happen if . . . ?
- What television programs do you normally watch?
- Why did you vote for Hillary Clinton in the 2008 presidential election?

Closed-ended questions, on the other hand, ask respondents to select from a given set of options provided by the researcher. For example,

Please circle your choice by answering "yes" or "no" to the following question:

Did you vote for Hillary Clinton in the 2008 presidential election?

Yes

No

Levels of Measurements

Media researchers have the option of using various levels of measurement to measure variables. There are four levels of measurement: *nominal*, *ordinal*, *interval*, and *ratio*. The nominal level of measurement is the weakest or lowest level, followed by ordinal, interval, and ratio level, which is the highest or strongest level of measurement.

Nominal is the weakest level of measurement because attributes of a variable can only be put in *categories* and assigned numerical values. For example, the variable

“sex” has two attributes, “male” and “female.” Here it is difficult to say which attribute ranks higher than the other. The kinds of statistical analyses that can be performed on a nominal level measurement are very limited.

The *ordinal* level of measurement is more precise than the nominal level. Here attributes of a variable can be ordered by rank but the distance between the attributes does not have any meaning. For example, respondents can be asked to rank their preference for a television program from 1 to 5. The researcher can then calculate which of the five programs is the most preferred of those given to respondents. However, he or she cannot conclude that the difference in preference for the television programs ranked 1 and 2 is the same as for those ranked 3 and 4.

The *interval* measures distance between the attributes, distance that has meaning. In media studies, verbal rating scales such as the Likert scales and the semantic differential scales are the most commonly used of interval scales.

The *Likert scale* is a five-point scale that was initially used by Likert to measure intelligence in survey research. However, since then it has been used for measuring various other subjective ideas. In this scale, respondents normally indicate their level of agreement on a scale of 1 to 5. For example,

I am satisfied with my cell phone carrier:				
1	2	3	4	5
Strongly disagree	Disagree	Neutral	Agree	Strongly Agree

Osgood, Suci, and Tannenbaum (1957) developed the seven-point *semantic differential scale*. It is a bipolar scale with contrasting adjectives at each end of the scale, for example:

This advertising campaign is:								
Very bad	1	2	3	4	5	6	7	Excellent

Ratio is the strongest and the most precise level of measurement. Ratio measurements have an absolute zero and the distance between the numbers is meaningful. For example, as on a measuring tape, the distance between 1 and 2 inches and between 2 and 3 inches is the same, and 2 inches is twice 1 inch. Income, age, years of experience, and length of stay are some examples of ratio level measurement. It is possible to have a zero income or zero years of experience. Ratio measurements allow for various kinds of mathematical calculations such as fractions, which can be useful for a researcher to gain precise insights.

Questionnaire Wording

In order to get complete and accurate information from the respondents, the questions should be clearly worded and free of jargon so that they mean the same thing

to every respondent. Media studies, like other fields, has its jargon and abbreviations which most people outside the field do not understand. These should either be avoided or clearly explained to the respondents.

When writing a question, it is best to use natural and familiar language, and the researcher should avoid inadequate question wording or asking “loaded” or leading questions, double-barreled questions, or questions with double negatives, in order to reduce errors and bias in responses.

Inadequate question wording is when a researcher does not ask a complete question. For example, the specific question “What was your age on your last birthday?” instead of just “Age?” (Fowler, 2009, p. 89) would elicit a more accurate response.

“Loaded” or leading questions bias respondents to think and respond in a particular way. Loaded words are usually emotionally charged words that bring out a strong positive or negative reaction. Calling a plant a weed brings out negative reaction toward the plant. Other examples include: “bureaucrat”/“public servant,” “pro-life”/“pro-choice,” “regime”/“government,” “estate tax”/“death tax,” “undocumented workers”/“illegal aliens,” and “elitist”/“expert” (Heller, 2002; Luntz, 2006). Leading questions force respondents to answer in a particular way. For example, a question phrased as “Don’t you agree that pilots should earn more money than they currently do?” leads respondents to answer in a particular way. It would be better to rephrase it as “Do you believe pilots’ salaries are a little lower than they should be, a little higher than they should be, or about right?”

Double-barreled questions often address two or more issues in a single question, which makes it difficult for respondents to answer accurately. For example, “Do you want to be rich and famous?” (Fowler, 2009, p. 94) and “Do you think the city should build more schools and parks?” The respondent might want to be rich but not famous. He or she might support the idea of building more schools but not parks. But these two questions do not offer respondents the option of responding to the two issues separately. It is thus important to ask the questions separately. The use of the word “and” in a question should be evaluated.

Double-negative questions – for example, “I disagree that children should not be allowed to participate in reality television program” – are confusing to respondents because they use two negatives in one statement.

In addition to these, *cross-cultural researchers* have to understand language, language subtleties, and common usage of words, signs, and symbols in another country in order to write a good questionnaire. George Bernard Shaw famously said, “England and America are two countries separated by a common language.” People from English-speaking countries such as the United States, the United Kingdom, and Australia often discuss their experiences of misunderstanding some of the common expressions, phrases, and words in each other’s country. Rubber can mean an eraser in one country (United Kingdom) and a condom in another (United States). Shoes can be called sneakers in one country (United States) and trainers in another (United Kingdom). Where language can be challenging even between English-speaking countries, the problem is compounded when designing a study for another country.

Language equivalency is important to establish in cross-cultural or global research. In global media research a master questionnaire is often designed, which is translated and used in different countries. In order to avoid mistakes relating to language and words, it is advisable to use the *back-translation method* (Brislin, 1970) to achieve accuracy in translation. In the back-translation method, two bilingual translators who are familiar with the source and target language are employed to translate the questions. One bilingual translator translates the questionnaire into the target language and the other translates it back to the source language to insure that there is no mistranslation. However, measurement errors can still arise because of the poor wording of questions, faulty cultural and other assumptions, and faulty scales.

In global surveys, questionnaires developed in one country should not be simply translated for use in another country. The researcher has to make sure that the concepts and scenarios presented in the questionnaire are understood by and relate to the local population in order to get results that are accurate and comparable. For example, Van Raaij (1978) notes that measuring social responsibility by asking “‘A good citizen is responsible for shoveling the sidewalk in front of his home,’ . . . assumes private ownership of houses, one-family housing, and a climate with snow in winter, and is clearly not applicable in an African country” (p. 693). The researcher will have to measure social responsibility in a different way in African countries. Similarly, questions about race that are commonly asked in the United States might make people in countries like the United Kingdom and South Africa uncomfortable and thus affect the response the researcher gets. In France, it is illegal to classify people by ethnicity or to ask census questions on race. Race as a category is meaningful only for multicultural countries like the United States, but not so much for a comparatively homogeneous country like Japan.

Questionnaire Structure and Appearance

It is important to keep the questionnaire simple and easy to read so respondents are not overwhelmed. Short instructions on how to answer the questions help the respondent. The opening questions should be easy, nonintrusive, nonthreatening, pertain to the respondent, and require little effort on the part of the respondent. This encourages them to continue.

A lot of white space on a questionnaire, a clear typeface, and logical flow from one topic to another help produce a better response. The flow of the questionnaire can be based on subject or topic areas, chronology, or any other criteria. It is better to move from general to more specific questions related to a topic area. Respondents often feel frustrated if they have to keep shifting back and forth between one topic and another.

Survey researchers often use *contingency questions* to help guide respondents through a questionnaire. Contingency questions act as a filter and allow respondents to skip questions that do not relate to them. For example, “Do you watch the televi-

sion program *Big Brother*? If ‘Yes,’ please continue. If ‘No’ skip to question number 5.” Even though contingency questions are helpful, they should be used only when necessary; too many skips can confuse respondents.

It has also been noted that survey respondents get tired, bored, uninterested, and unmotivated after going through a series of questions. When this happens, respondents tend to answer “Don’t know,” engage in “straight line” responding (i.e., choose answers from the same column on a page), give more perfunctory answers, or give up answering the questionnaire altogether (Ben-Nun, 2008). In order to avoid *responding fatigue*, it is important to have a variety of questions. On a scale using a large set of agree/disagree items, *item reversal* (see Paulhus 1991) can help the respondent to pay attention and prevent straight-line responses.

After designing the questionnaire, it is important to pretest or pilot-test the survey before collecting the data. This will help identify the problems with the questionnaire before it is used.

Challenges in Survey Methodology

Survey methodology relies heavily on self-report or other-report and thus inaccuracies often arise due to the misreading of questions by respondents, inadequate knowledge, faulty or invalid answers, and inability to recall incidents, products, or advertising. According to De Mooij (2010, p. 143), “[p]eople may sometimes not say what they think; they may distort their answers for various psychological or cultural reasons or misinterpret some questions. The way questions are formulated can cause bias. The answers may not accurately reflect people’s feelings or behaviors in actual social settings.”

Telephone surveys, which were once quite popular when people had landlines and one national telephone company monopolized the market, are becoming less popular with the growth of mobile phones and for a number of other reasons. Researchers no longer have one good sampling frame to study households, as mobile telephone numbers are not attached to a geographic location but to a mobile individual. Today there are multiple carriers, and people transfer their number across state lines, thus making it difficult to have a good sampling frame. In addition, the nonresponse rate seems to be higher for mobile phones than for landlines, perhaps because people have a greater ability to screen calls (American Association for Public Opinion Research, 2008). In addition, the Do Not Call registry in the United States, and the Telephone Preference Service in the United Kingdom, prevent telephone survey researchers from calling a larger number of people who do not wish to be contacted. This further affects the sample frame. Groves (2011, p. 869) notes, “Although there appears to be a broad consensus among survey methodologists that we are moving to a future of mixed-mode surveys, the current available mix does not solve the problem of falling response rates in a permanent way.”

Managing Response Rate

In survey research it is important to reach and collect data from every individual in the sample. Failure to do so results in errors and skewed findings. Response rate is affected when respondents do not answer a particular question on a questionnaire or do not fill in the questionnaire at all. Response rate is also affected when the survey does not reach the respondent (*noncontact*), or when the respondent is unwilling or unable to participate due to illness or other reasons (*nonresponse*). These result in *nonresponse errors*. Repeated calling of unanswered telephone numbers or repeated contacting of eligible respondents can improve response rate. For more details on improving response rate, see Groves, Dillman, Eltinge, and Little (2002) and Dillman (2007). Response rate is important for researchers to report so that readers can evaluate the quality of the research. The simplest way to calculate response rate is by dividing the number of people who completed the survey by the total number of individuals or units in the sample.

In survey research, there is no consensus on what response rate is acceptable (American Association for Public Opinion Research, n.d.; Fowler, 2009; Langer, 2003). The American Community Survey reports a high response rate of 97.6 percent (US Census, 2013). Many surveys can be found with a response rate as low as 20 percent. The Division of Instructional Innovation and Assessment at University of Texas at Austin (2007) notes, “acceptable response rates vary by how the survey is administered.” For mail surveys DIIA notes, 50 percent response rate is considered adequate, 60 percent is good, and 70 percent is very good. For phone surveys, 80 percent is considered good; for email surveys, 40 percent response rate is considered average, 50 percent is good, 60 percent is very good; for online surveys, 30 percent is considered average; and for face-to-face surveys, 80–85 percent is considered good.

As mentioned, cross-cultural survey researchers face additional challenges. One such challenge deals with the use of standard measurement scales. De Mooij (2010) notes that this might be problematic as the conceptual model on which the measurement scales are developed often do not relate to another country in the same way. In addition, people in different countries differ in their *response styles* (Baumgartner & Steenkamp, 2001). For example, Italians have an *extreme response style* (ERS) in that they tend to choose extreme points in verbal rating scales and Germans tend to mark toward the middle (De Mooij, 2010). Thus a “completely agree answer in Italy is not worth the same as completely agree answer in Germany” (De Mooij, 2010, p. 147). Similarly respondents in the United States tend to start from extreme positions on a verbal rating scale of “excellent” to “terrible” and then move inwards, while the Japanese respondents start with a neutral point and work outwards, rarely taking an extreme position (Fields, quoted in Mueller, 2010). Thus establishing *metric or measurement equivalency* is often difficult.

Conducting Ethically Sound Survey Research

Survey research methodology can yield valuable information that can help in making important decisions. Thus survey researchers need not only to follow the best procedures for conducting a survey, but should also conduct the surveys ethically so that no harm comes to respondents. Survey researchers also have an ethical obligation to their client for whom they are conducting research, to the interviewers, and to the company or institution for which they are conducting the survey.

The researcher needs to be open and honest with the client about the study, how it will be conducted, who will be surveyed, and how much time and cost will be involved. If any issue arises and compromises are made along the way, those need to be communicated to the client. The report to the client should be an accurate reflection of the data and not based on what the client hopes to hear. The researcher also has an ethical obligation toward those who work for him or her. The researcher needs to train the interviewers well so that they can conduct the survey in a professional manner. The researcher also needs to deal with any safety and security concerns of the interviewers. Interviewers should not be pressured into going into areas that are not safe. Finally, the researcher needs to do his or her job professionally and with the highest ethical standards in order to help his or her company or institution gain credibility and reputation.

In the United States, in order to protect the research participants, studies done in universities have to be approved by the institutional review board (IRB) before they can be conducted. The guidelines followed by the IRB for protecting human subjects come from the Belmont Report of 1979, which was put together after a series of research that were ethically compromised (US Department of Health & Human Services). The syphilis study in Tuskegee, Georgia (1932–1972), thalidomide use, radiation experiments (1940s–1960s), and the Milgram study (1963) are some well-known studies that raised ethical concerns. After the publicity from the Tuskegee syphilis study, the National Research Act of 1974 was passed, which created the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. The commission in its report articulated three principles for protection of human subjects: informed consent, assessment of risks and benefits to the participant, and fair procedures and outcomes in the selection of research subject. Even though most media survey research falls under the “exempt” category, the procedure for approval as well as protection of participants needs to be followed. If the research involves collecting data from a vulnerable population such as children, pregnant women, prisoners, and the mentally ill, extra precaution needs to be taken to protect these participants from risk or harm.

In survey research, *informed consent* means providing respondents with information about the study before getting their consent for voluntary participation. Informed consent often includes providing respondents with the name of the organization

conducting the research, the name of the researcher, the name of the organization sponsoring the research, a brief description of the study and the purpose of the study, an indication the time it would take to fill out the survey, options to skip questions that respondents do not wish to answer, and information on how anonymity and confidentiality will be maintained (Fowler, 2009). These are often written in the *consent form* that the respondent reads and signs or consents to before participating in the survey.

Maintaining *anonymity* and *confidentiality* in survey research is extremely important to protect the participant from harm. Lack of anonymity and confidentiality can compromise a respondent. For example, a survey collecting workplace data can identify employees to the managers, putting their jobs in jeopardy. Thus, information about the respondent should not be shared with anyone other than the research team. Either personal identifiers such as names, emails, telephone numbers, and home or office addresses should not be collected, or the survey data and the identifying information should be kept separate. Data should be kept in a secure location, and any identifying information should be deleted or destroyed after the survey has been conducted.

In very small number of cases involving drugs and crimes, subpoenas (court orders) have been issued for records and data from the researcher. This can compromise confidentiality and the anonymity of the respondents. Thus it is important to destroy any identifying information as soon as it is no longer needed (Fowler, 2009). Second, a *certificate of confidentiality* should be obtained from state or federal agencies for protection from subpoenas if the research involves collecting data on biomedical or illegal activities (see Sieber, 1992, for more details). In the United States, government agencies such as the National Institutes of Health (NIH) and the Department of Health & Human Services issue certificates of confidentiality.

Ethical principles require that the clear *benefits* of the research to the research participants be stated. In survey research, the participant can get benefit from the process itself by feeling that he or she has contributed to the understanding of the topic. He or she can also gain benefits in the form of gifts, payments, or prizes. Gifts, payments, or prizes should not be so large as to compromise voluntary participation. People who need the money might feel compelled to participate even though it may not be in their best interest.

The ethical principle of *justice* articulated in the Belmont Report (US Department of Health & Human Services, 1979) requires fairness in procedures and outcomes in the selection of research subjects. This is particularly important for survey researchers because survey methodology involves selecting a sample for the study. The Belmont Report notes that the selection of subjects should not be such that it compromises fairness. It states that researchers should not

offer potentially beneficial research only to some patients who are in their favor or select only “undesirable” persons for risky research. Social justice requires that distinction be drawn between classes of subjects that ought, and ought not, to participate in

Beyond the Qualitative/ Quantitative “Divide”

Reflections on the Utility and Challenges of Q Methodology for Media Researchers

Carolyn Michelle and Charles H. Davis

ABSTRACT

This chapter introduces readers to Q methodology, a methodological hybrid concerned with revealing similarities and differences in people's viewpoints, attitudes, beliefs, and experiences. The history of Q methodology is first outlined, and its key principles and processes are explained, before a brief case study is presented in which Q methodology was used in an online survey of cross-cultural responses to James Cameron's 2009 feature film *Avatar*. Here, readers are taken behind the scenes to reflect on the methodological challenges faced, while some of the unique insights that Q methodology provided in this case are highlighted. Finally, the major strengths and limitations of Q methodology are discussed. It is an approach that has considerable potential to shed light on many key questions in contemporary media studies.

Introduction

This chapter aims to introduce readers to a relatively little-known methodology within media studies, one we believe has much to offer those interested in under-

standing the subjective dimensions shaping media production, reception, consumption, and use. Q methodology can be described as a methodological hybrid that is neither qualitative nor quantitative, but draws on some of the strengths of both traditions. It thus combines the mathematical rigor of quantitative methods with a strong interpretive component more typical of qualitative approaches to human research (Stainton Rogers, 1995; Stenner, Watts, & Worrel, 2008; Watts & Stenner, 2012). Q methodology is primarily concerned with revealing similarities and differences in the viewpoints, attitudes, beliefs, or experiences of participants, and does so in a way that is relatively systematic, reliable, and replicable. Furthermore, by deploying Q methodology's unique capacity to reveal shared subjectivity in conjunction with a more traditional questionnaire seeking details of respondents' sociodemographic memberships (gender, age, ethnicity, occupation, and so on), discursive affiliations, and political interests, it is possible to explore whether and in what ways shared viewpoints might be related to aspects of identity and subject positioning. For these and other reasons, we believe Q methodology has much to offer critical media scholars located within a range of disciplines.

In this chapter, we briefly outline the history of Q methodology and explain some of its key principles and processes. Following this, we present a brief case study of our recent experience using Q methodology in an online survey of cross-national responses to James Cameron's 2009 feature film *Avatar*. We take readers behind the scenes to offer our personal reflections on some of the issues and challenges researchers may confront when using this method. We also highlight some of the unique insights that Q methodology offers, which we hope will provide useful guidance for emerging researchers interested in adopting this approach. Finally, we discuss some of the main strengths and limitations of this method, and outline why we believe Q methodology may have unique potential to shed light on some of the key questions in media studies today.

What Is Q Methodology? A Brief History and Overview

Q methodology was created by psychologist-physicist William Stephenson in the 1930s as a structured research tool designed to analyze the nature and diversity of people's attitudes, perspectives, or subjective experiences relating to a given topic (Stephenson, 1953). He conceived it as an alternative to existing methods used to measure attitudes within psychology, which typically relied on the researcher's *a priori* categorizations and other normative considerations (Brown, 2006). An exploratory empirical research method, Q methodology can elicit insight into human subjectivities in the rich and holistic way more typically associated with in-depth interviews and focus groups, while also providing clear structure, capacity for replication, and robust measurement-based analysis. In Q research, participants are given

tools with which to express their own priorities and understandings, from their own particular standpoint. Rather than imagining infinite variability among people's perspectives, however, Q methodology presumes a finite degree of diversity in viewpoints (Stainton Rogers, 1995). It aims primarily to identify and chart the nature and range of distinct subjective perspectives on a given topic that are shared by groups of individuals, reflecting an objective substructure or "defined set of interpretations" (Brown, 1977, p. 572) that occur naturally, rather than being the result of the researcher's prior categorizations.

While Q methodology has grown in prominence within disciplines such as psychology, tourism and environmental studies, political science, communication studies, policy studies, marketing, and health sciences, it remains on the margins of media studies scholarship, and is frequently neglected in methodology handbooks within this discipline. But, as we hope to illustrate in this chapter, Q methodology has considerable potential to offer insight into many aspects of media production, reception, consumption, and use. We believe it constitutes a very useful addition to the media researcher's methodological toolkit, while also offering a new way of approaching some of the lingering questions in the field.

How Does Q Methodology Work?

In brief, participants are first invited to "map" their own viewpoint on the topic by responding to a diverse selection of relevant ideas and opinions. These "maps" are then collectively analyzed to identify *factors*, which reveal that particular groups of individuals share a similar perspective on the topic in a more holistic sense, in that they tend to generally agree and disagree about the same things. Of course, this process is a little more complex in practice.

In a typical Q study, a research question is first formulated. Q methodology particularly lends itself to research questions "that have many, potentially complex and often socially contested answers" (Stenner et al., 2008, p. 219). The kinds of questions that Q methodology may assist in answering are among the key ones for contemporary media researchers. For instance: what are the subjective influences that shape the creation, production, and consumption of media content? How do the perspectives, beliefs, and motivations of the producers of media texts inform their professional and creative practices? How do people make sense of and use different forms of media? How do media representations inform people's understandings and evaluations of themselves and of the wider world? What is the place of media in people's everyday lives? What kinds of consumption patterns and cultures of use are evident in relation to traditional media, compared to new digital media forms? How do people experience and respond to growing degrees of media convergence? What motivates people to become creators of media in their own right, and what are the conditions that stimulate such "produsage" (Bruns, 2008)?

Once a question is determined, the researcher generates a list of items to sort (the *Q sample*), which is a broadly representative sample of self-referential and subjective statements drawn from the wider discursive field that surrounds the issue or topic under investigation, referred to as the *concourse* (Stephenson, 1985). The concourse “consists of all that can be thought and said about a situation, event, or phenomenon” (Durning & Brown, 2007), and includes diverse statements of subjective opinion that constitute a part of the “oral public culture” relating to the topic at hand (Fiske, 1987, and Bondebjerg, 1988, cited in Stephenson, 1995–1996). In *Q methodology*, individuals are assumed to formulate their own perspectives with reference to the ideas and perspectives that are circulating within the wider field of discourse, with which they will be familiar but not necessarily agree (Stephenson, 1995–1996).

Usually, the *Q sample* items comprise short statements – just a sentence or two expressing one coherent idea or perspective – derived from in-depth interviews or questionnaires with a wide range of individuals, or perhaps from published sources such as academic criticism or letters to the newspaper, or even online sources such as reviews, news items, or discussion forum comments. The researcher can seek suitable *Q* items from wherever the concourse around their topic is thought to exist, and in whatever form it is most often expressed. Depending on the topic, images, objects, or other stimuli such as sounds can also be sorted. The most complex case reported in the literature on communication, media, and audiences is Grosswiler’s (1992) multimedia *Q sample* used to investigate the theory, articulated by Marshall McLuhan and others, that the emergence of new media forms generates related shifts in human values and consciousness. Grosswiler’s *Q sample* included items from newspapers, magazines, literature, art, and poetry, as well as audio and video recordings. In a subsequent study, Grosswiler’s respondents sorted slides of magazine and newspaper front pages, videotapes of television program excerpts, and audiotapes of radio program excerpts in a way that reflected their preferences for certain kinds of media content (Grosswiler, 1997; see also Rhoads, 2009). Whatever their form, all the items used are generally carefully selected and considered by the researcher in relation to each other in order to attain a *Q sample* that represents, as much as possible, a very wide spectrum of suitable stimuli, most often in the form of subjective responses to the given topic, from multiple different angles.

Since respondents must compare each item with all other items and the number of possible pairwise comparisons is vast, the researcher usually selects a smaller number of items from an initial survey of the wider concourse for the final *Q sample*. Items may be selected in a structured way, perhaps to represent categories associated with an existing theory, or more commonly in an unstructured, representative way (Dziopa & Ahern, 2011; McKeown & Thomas, 1988). The chosen items are presented individually on cards, or represented on virtual cards if conducting the survey online.

Next, the researcher selects the respondents (called the *P set*). Nonrandom sampling is used to select a population of individuals who are likely to have quite different views about the topic, or who represent theoretically relevant subpopulations. For instance, a researcher may endeavor to select a wide range of individuals who are

diverse in terms of their gender, age, education, political or religious orientation, or areas of expertise (McKeown & Thomas, 1988, pp. 38–39). Unlike conventional quantitative survey methods, it is not necessary to include a large number of respondents, and most Q studies have only a few dozen respondents (Danielson, 2009). Stainton Rogers (1995) suggests between 40 and 60 participants is optimal in terms of maximizing the range and diversity of viewpoints.

Once selected, each respondent is asked to create a map or model of his or her viewpoint using the items the researcher has selected from the concourse. Respondents rank-order the numbered items in the Q sample according to a condition of instruction, such as from “most strongly agree” to “most strongly disagree.” The convention in Q methodology is that the items be sorted into a quasi-normal distribution – roughly in the shape of a bell curve – which can have several degrees of agreement with the neutral or indifference point in the middle, as in the example of a 32 item sort shown in Figure 4.1.

Respondents are asked to first sort the items into three piles – disagree, neutral, or agree – before selecting the few items with which they *most strongly agree* and *most strongly disagree*, placing these at either end of the set distribution. They then continue to place all the items, gradually working their way toward the middle (see Brown, 1986, 2008; McKeown & Thomas, 1988; Watts & Stenner, 2012, for a fuller description). Having hopefully provided the same *kinds* of discursive resources available within the wider concourse, the researcher steps back to allow participants to determine for themselves the value, meaning, and significance of the different items from their own unique point of view, and to express this through their ranking and placement of statements on the grid. The final configuration is taken to represent a holistic expression of their subjective experience or perspective, at least in as far as it is possible to express this, given the items made available to them – this is why careful selection of the items in the Q sample is crucial. The positioning of each item on the grid is then recorded.

Figure 4.1 Example of a 32 item Q sort grid

Individual Q sorting is generally administered in person, using physical cards containing the Q items and a large grid on which these can be arranged. However, online Q research using dedicated software such as FlashQ is increasingly practiced. This software visually replicates the card sorting and ranking process on screen through a user-friendly interface, guiding respondents through each stage of the process as they finalize the arrangement of the various statements on the virtual grid. This software also makes it possible to include a tailored questionnaire for respondents to complete, which can collect relevant sociodemographic data and/or information about personal attributes the researcher suspects might be relevant. The software then captures all the data for each individual and records it in a format that can easily be imported into an Excel spreadsheet, which makes it very easy for the researcher to “eyeball” the data.

The process of sorting the items is normally followed by asking respondents to explain in further detail their reasons for selecting the “most strongly agreed” and “most strongly disagreed” items. In an online Q survey, respondents are usually invited to write some additional comments on why they chose each of those items in open text boxes. This is an important step that aids the researcher in interpreting the results, and often elicits rich qualitative information about unique aspects of the subjective perspective of each respondent (Davis & Michelle, 2011; Schröder & Kobbernagel, 2010). However, eliciting rich insight is somewhat more problematic when conducting Q studies online, since it relies entirely on respondents’ willingness to offer further comments, and some may prefer not to do so – although in our experience the vast majority do make additional remarks. The online Q researcher is also less able to gauge respondents’ reactions to particular items and to the process of ranking the statements while the research is in process. But as we shall discuss further below, online Q sorting also has some distinct advantages, and future technological enhancements may offer ways of overcoming these kinds of problems.

The full set of individual Q sorts is then analyzed to identify associations between respondents on the basis of their rank-ordering of the Q items. A matrix of correlations among the Q sorts is created which is then factor-analyzed – by *person* and with reference to the entirety of their arrangement of the Q items, not by discrete items – to identify those respondents whose Q sorts are significantly similar, in that they independently ranked and arranged the same items in much the same way on their own grid. In this way, it becomes possible to systematically identify and describe the range of distinct viewpoints, perspectives, or orientations that are shared by different groups within the sample (see Brown, 1994; Dziopa & Ahern, 2011; Stainton Rogers, 1995; Watts & Stenner, 2012). While it may sound complicated to the uninitiated, there are now dedicated Q methodology software programs available that are relatively user-friendly and handle much of the serious number crunching. PQMethod is available for free, while PCQ, a commercial software package, is also widely used (see the Q method website at www.qmethod.org for hyperlinked resources). PCQ and PQMethod handle the statistical computations that occur during factor analysis, and provide various factor solutions while enabling the researcher to perform

additional tests on the data. Further information about these analytical procedures can be found in McKeown and Thomas (1988) and Brown (2006).

The researcher then interprets these factors by synthesizing all of the data to “tell the story” of how those individuals who loaded significantly on each factor commonly responded to the condition of instruction. This interpretation considers areas of strong agreement, disagreement, and neutrality, and notes points of similarity and difference between the factors. The quality of the interpretation thus largely depends on the researcher drawing on his or her accumulated knowledge and expertise to consider the significance of how respondents have ranked the different statements *in relation to each other*, and in this they are guided by the respondents’ own explanations of *why* they most strongly agreed or disagreed with particular items. A written narrative encapsulating the defining features of each perspective is produced for each factor, which usually incorporates examples of participants’ explanatory comments as additional supporting evidence for the validity of the interpretation, and to add depth and texture to the analysis. Such statements help restore some of the “discursive meat” to the “analytical skeleton supplied by the factor analysis” (Schröder & Kobbernagel, 2010, p. 126). What emerges from this process is a more holistic representation of a finite range of complex, multifaceted, yet still coherent viewpoints on the topic under investigation. This is one of Q methodology’s key strengths, and we believe it makes the Q method particularly suitable for research investigating the subjective perspectives, beliefs, experiences, and practices of media producers, audiences, consumers, and (prod)users.

Utilizing Q Methodology in Media Research

Indeed, although Q methodology remains on the margins of mainstream media studies, a growing number of scholars are using this method in studies of media production, consumption, interpretation, and use (see Davis & Michelle, 2011). Significantly, Stephenson himself explicitly applied Q to reception analysis in advertising and screen audience studies (Stephenson, 1976, 1978, 1995–1996). To give readers a taste of the kind of work being done, consider Robinson’s (1975) Q study of the attitudes expressed by upper middle-class professionals toward television and film, a group that had previously been considered unenthusiastic and critical viewers of screen media. Robinson found that, while there were some shared attitudes among the respondents, a broad-brush demographic distinction based on socioeconomic class obscured important differences in tastes and media preferences which tentatively appeared to be more specifically shaped by occupational memberships. Six distinct types of viewers were identified, including scientifically inclined “information absorbers” and more legally oriented “community leaders,” both of whom sought escape and tended not to actively interpret information from television. Other groups

included “analytical artists” and “film freaks” which were highly selective and analytical in their viewing; primary loaders in these categories were university professors.

Carlson and Trichtinger (2001) used Q methodology in a study of viewers’ subjective reactions to the characters and themes portrayed in an episode of the US television series *Law and Order*, which was a fictionalized account based on a real-life racial incident. They discovered seven distinct “readings” of the episode that appeared to engage in quite different ways with the message and thematic content of the text, reflecting the interaction between limited textual polysemy and the capacity of viewers to determine “what aspects of the conversation are heard, assimilated, and made part of a subjective political reality” (Carlson & Trichtinger, 2001, p. 270). The authors also identified suggestive links between the viewpoints and the racial and ethnic identities of participants who positively or negatively loaded on those factors.

More recently, Schröder and Kobbernagel’s (2010) study of cross-media news consumption by 35 Danish consumer-citizens identified seven types of users and found tentative correlations with age, education level, gender, and whether the respondent lived in an urban center or a provincial town. Predominant “types” included more traditional, versatile news consumers, popular culture-oriented digital news consumers, light newspaper readers, and news update addicts. The authors argue that the typology generated using Q methodology offers a more complex picture of the subtle distinctions between consumer perceptions and consumption of news media than has been suggested by other large-scale quantitative surveys.

A case study of Q methodology in action may offer readers further insight into the Q research process. In what follows, we focus on our recent research exploring cross-cultural receptions of James Cameron’s 2009 movie blockbuster *Avatar*, taking the reader behind the scenes to offer more specific insight into this method and its capacity to illuminate the nature and content of human subjective responses, along with its ability to generate unexpected findings.

Receptions of Avatar: A Case Study in Using Q Methodology for Media Research

In this study, we were interested in understanding the nature of people’s subjective responses to a film that, while generally well received and certainly extremely popular internationally, had also been critiqued on a variety of grounds. While people clearly had many specific opinions about the film, what was their overall response, in a more general and holistic sense? Did viewers in different countries have basically similar kinds of responses, or were there major cross-national distinctions? Were different responses in some way linked to aspects of viewers’ location and sociodemographic attributes, or did other more relevant discursive affiliations perhaps cut across those broad-brush classifications? How well might existing theoretical understandings

about the nature of audience reception predict and “capture” naturally occurring demarcations in the responses of our participants?

In the initial stages, we conducted an intensive “cultural trawl” of the wider course around *Avatar* by drawing on online professional and lay film reviews, fan website discussion boards, Facebook site message boards, international news coverage, and media commentary to gain a very broad and inclusive impression of the diverse subjective responses to *Avatar* within the public domain. Throughout this process, recurring patterns in the content and tone of the views expressed were noted and archetypal statements relating to the film’s explicit and implicit messages, dominant and marginal themes, aesthetic quality, production values and imperatives, intellectual analysis, and emotional reactions were cut and pasted into an Excel file.

From an initial pool of 260 “raw” statements articulating recurring ideas, opinions, or reactions expressed in various different sites, it was necessary to make further selections for the Q sample. Rather than adopt a random selection process, this study used a structured sampling method grounded in a particular theory. Other Q audience studies have used different theoretical frameworks to guide the selection process, such as Holbrook’s (1999) framework of consumer value (Davis & Vladica, 2010); generally the choice of model reflects the specific focus of the study. In this research, because our interest lay with charting the nature of any distinctions in the subjective responses of *Avatar* viewers, we drew on Michelle’s (2007) composite multidimensional model of audience reception. The captured statements were thus reviewed and loosely categorized according to this particular schema, which synthesizes a range of existing conceptual frameworks and research findings, identifying broad distinctions in the subjective responses of different individuals and groups to a range of screen media texts and genres viewed in various cultural contexts. Such distinctions are reflected, for instance, in Hall’s (1980) model of encoding/decoding which identifies the potential for dominant, negotiated, and oppositional readings; Liebes and Katz’s (1990) analytical distinction between critical and referential readings; and recent work in media effects research on narrative transportation (see Michelle, 2007, 2009; Michelle, Davis, & Vladica, 2012).

Taking care to preserve as much of the original diversity of responses as possible, an initial cull systematically reduced the number of Q statements to 48, eliminating as much repetition of themes and content as possible. In the course of a face-to-face pilot study conducted with 24 respondents in the city of Hamilton, New Zealand (pop. 131,000), these statements were progressively re-evaluated and revised to insure each expressed relatively unambiguous ideas or themes and to eliminate further redundancy among the statements. Gradually, the statements were whittled down to the final Q sample. For each of the four modes theorized in the composite model (transparent, referential, mediated, and discursive) eight items were finally selected. The final 32 item Q sample was thus constituted with a dual purpose: (1) to reflect as much as possible the diverse range of subjective perspectives circulating around this mainstream entertainment text, and (2) to operationalize a theoretical model of the different modes of audience reception developed by one of the authors. This

renders our study somewhat unusual, but also offers insight into the kind of potential Q methodology may have for exploring and refining media theory.

Participants performed their Q sorts online with the free software application Flash Q, and before submitting their responses were invited to complete a “personal details” questionnaire seeking information about their sociodemographic memberships (gender, age, nationality, ethnic identity, education level, and occupation), acquired media competencies, fandom, political affiliations, religious beliefs, and military experience. We sought this information because we were curious whether these kinds of factors might be linked to different modes of response to the film, given some of the reactions expressed in the wider concourse. We were also interested in exploring the potential uses of Q for linking modes of reception to the intersection between relevant aspects of viewers’ social location.

The *Avatar* Q sort went live online on May 18, 2010, and was open to English-speaking participants with Internet access anywhere in the world. Immediately before carrying out their Q sort, participants read a set of instructions on screen which stated that the researchers wished to know how they responded to and felt about *Avatar* when they first saw it. As the condition of instruction, they were asked to “Please recall the thoughts and feelings you had immediately after watching *Avatar* while you rank the following statements.” After first reviewing and sorting all the statements into three piles – disagree, neutral, or agree – they were instructed to arrange the 32 statements on a continuum from “most strongly agree” on the right to “most strongly disagree” on the left in a forced normal distribution. Respondents were also invited to provide a written explanation for why they selected the four statements they placed at each end of the scale. These qualitative comments were crucial in guiding our interpretation of the subjective viewpoints that emerged, and we incorporated typical comments into our descriptions of the factors.

While conducting a Q study online has its advantages, there is some debate in the Q community about the suitability of a technologically mediated approach to studying human subjective responses – an issue to which we shall return below. In the case of our study, we specifically sought to reach an international population of respondents in order to glean some insight into the cross-cultural applicability of a particular theory, but were also constrained in terms of available resources; hence an online survey open to participants from any country seemed desirable, but it did present some challenges. One of the key difficulties we faced was accessing a suitably diverse range of participants for the P set, since presumably those most highly motivated to participate would be more likely to be *Avatar* fans rather than critics. Online surveys naturally attract more highly motivated respondents and are likely to over-represent the views of those who have a keen interest in the subject matter, potentially amplifying one particular perspective. To counter this tendency and obtain a more diverse P set, we actively encouraged participation from a wider range of viewers by posting invitations to participate on the “*Avatar* Sucks!” Facebook group message board, and on general film discussion boards such as Rotten Tomatoes. Special interest groups were also targeted via active Facebook groups such as Survival International, the

Indigenous Environmental Network, Military.com, and Conservative Americans United. Invitations were also posted on key fan sites such as Avatar-forums.com, and on Facebook fan group sites such as the Official *Avatar* Movie group.

Despite our efforts, fans rather than critics were clearly more motivated to participate: over half of the 89 significant sorts reflected the same very positive viewpoint, with many of these participants being self-declared fans of the film. Nonetheless, we clearly did secure a number of participants who were harsh critics. Because an online survey solicits participants who are self-selecting, there is a case to be made for using somewhat larger online P sets, from which a smaller number of more representative sorts may be obtained for the factor analysis, with selections being based on particular sociodemographic characteristics, or perhaps more usefully, the stated discursive affiliations and interests of respondents in relation to the topic at hand, which is somewhat akin to the practices normally used to select a nonrandom P set for face-to-face sorting. This information can be easily obtained through the personal details questionnaire that accompanies the Q sort in programs such as FlashQ.

Since respondents were primarily recruited through online communities, our sample consisted of people who are active on the Internet. Recent estimates suggest that this now accounts for 75–90% of people in most Western developed nations (Internet World Stats, 2009). Nonetheless, online research of this nature is likely to over-represent the views of what Hannerz (1990) called Internet savvy “‘cosmopolitans’: people whose life orientation revolves around global interconnectedness rather than their local communities” (Kuipers & de Kloet, 2009, p. 104) – and these are likely also to be relatively economically empowered individuals, especially in developing nations. This bias appears to be a significant limitation of online research generally, and was evident in our *Avatar* sample. Aside from a large number of university students, relatively few respondents reported earning low incomes or having blue-collar occupations.

One perhaps more significant problem with conducting an anonymous Q study online relates to the problems posed for interpreting the results, given that the researcher is not present to observe participants’ responses during the sorting and ranking process, and is not able to question them about any strong reactions to the items as they occur, which would normally happen in face-to-face sorting. This issue is currently hotly debated in the Q research community. Information gained from face-to-face Q sorting can be very useful – seeing when and why a participant seems unsure or has trouble deciding, or reacts strongly to particular items, can aid in interpreting the particular configuration of items for that person. However, in our study, we were more concerned with identifying the range of viewpoints within the international audience for *Avatar*, and unfortunately this precluded being able to observe the sorting process directly, although we agree that it is desirable to do so where possible. Such observations were, however, possible during the face-to-face pilot study, where the ability to observe and inquire about participants’ verbal and nonverbal reactions proved very helpful in identifying statements that were ambiguous, unclear, or insufficiently distinct from others.

While there are related concerns within the Q community that the technological mediation of online Q sorting potentially changes and degrades the process of accessing and understanding human subjectivity in its “original” untainted state, we believe, perhaps controversially, that it may be possible to at least partially mitigate such objections by more fully utilizing modern technological developments, and particularly the now widespread availability of inbuilt web cameras in many computers and laptops. Potentially, the researcher could observe the process and even interact with the respondent live, as now frequently occurs with the use of Skype and other video conferencing tools and applications. In other words, the technology now exists to make the researcher virtually “present” in the online sorting process, if not physically so. For those studies where it is particularly important that each respondent be observed, there is the capacity to do so regardless of the participant’s physical location.

Obviously, recording the sorting process in this way will likely impact participation rates, particularly when respondents are self-selected. There may also be some topics for which the anonymity and independence offered by anonymous online Q sorting might be quite advantageous, as it may lessen the incentive for participants to engage in impression management, and may also reduce any perceived embarrassment about expressing their true opinions on controversial or deeply personal topics. In other words, depending on the topic, it may be appropriate to adopt different research strategies that offer greater or lesser degrees of anonymity, and in which the researcher is more or less “present” in the process, depending on how important direct observation is deemed to be and its possible impact on respondents.

It is also important to acknowledge here one other possible effect of technologically mediated applications of Q, one that relates more to the limitations of visually presenting Q items on screen. In face-to-face Q sorting on a table, the respondent can easily see the entire array and make the necessary holistic comparisons visually. But with online Q sorting, the smaller the screen, the smaller the Q item cards, and the less text is visible on each of them; the readability of the cards is potentially compromised. This may well affect the respondent’s ability to make the many-to-many holistic comparisons which are the foundation of Q methodology. This is a technological pitfall that the researcher should be aware of. Ideally, Q sorts should be performed on a large computer screen where possible. Given recent trends toward screen miniaturization it seems that in the future, online Q sorting software may need to be modified or even completely redesigned to suit different formats, while still adhering to Q sorting conventions – a potentially significant challenge.

Despite these contentious methodological issues and other difficulties encountered along the way, our results provided a fascinating insight into the clear distinctions between *Avatar* audiences and even between fans themselves. Factor analysis revealed four distinct subjective orientations characterized by differing degrees of emotional and cognitive involvement, as well as different foci in terms of the most salient issues and concerns for particular groups of viewers. These four viewpoints

accounted for 74% of our 120 participants, and there were a number of others whose Q sorts were mixed in the sense that they bore similarities to more than one viewpoint. What was more exciting from our perspective was that these factors appeared to exhibit notable similarities to the four modes of reception theorized in the composite model of reception. Whereas Factor 1 was marked by suspension of disbelief, feelings of being transported to the amazingly realistic world of Pandora, emotional engagement with the Na'vi's plight, and agreement with preferred messages, all key aspects of the theorized transparent mode, Factor 2 exhibited estrangement and emotional detachment, with these viewers rejecting *Avatar* as an overcommercialized Hollywood entertainment product while also engaging critically with the film's ideological or message content – a defining feature of the discursive mode. While Factor 3 focused attention on the film's similarity and relevance to past and present struggles occurring in the real world against Western imperialism, militarism, and capitalist exploitation of natural resources, and thus appeared to be framed by a referential mode, Factor 4 related primarily to *Avatar* as a constructed entertainment media product which was aesthetically pleasing and technologically remarkable, but had significant shortcomings in terms of script and storyline – a response that is fairly typical of those adopting a mediated mode of reception. Each viewpoint appeared to reflect a very different subjective approach to making sense of the same film, and focused on different levels of denotative and connotative meaning, as theorized in the composite model of reception.

Two of the viewpoints had inverted or bipolar versions, in that a few participants reacted to the same kinds of ideas and themes in diametrically opposed ways to most others. For instance, while most of those who loaded significantly on Factor 3 saw the film as essentially quite realistic and true to life in the sense of mirroring processes of colonial and military oppression and the exploitation of indigenous peoples or the environment here on earth, a few reacted most strongly *against* this aspect of the film, and considered its depiction to be historically inaccurate and highly unrealistic, even a *distortion* of real-world events. In theoretical terms, both can be considered variations of the same referential mode of response, since both viewpoints primarily rely on the viewer making assessments of textual realism with reference to their knowledge and understanding of the real world outside the text.

Another key finding was that those who had a very positive view of *Avatar* did not all have the same response to the film. While some were “swept away” to another world and felt deeply emotionally engaged with the plight of the Na'vi, others responded positively to the film as a realistic reflection of real-world events, and still others were most impressed by the technical and aesthetic features of the film, especially the computer-animated visual effects, but remained more emotionally detached. This finding is important as it offers insight into the complex nature of audiencing, which is not necessarily premised on the same kinds of experiences and emotional, aesthetic, and intellectual responses, but rather can take diverse forms and may focus on radically different aspects of the same media text (see Michelle et al., 2012, for full details).

We were also able to discern some suggestive associations between particular viewpoints and shared sociodemographic characteristics such as gender and ethnicity, as well as other suggestive influences grounded in life experiences and discursive affiliations, including level of education, religious belief, political activism, and military service (see Michelle et al., 2012). Namely, those who read the film in referential or discursive terms were more likely to be politically active professionals and to identify themselves as a member of an ethnic minority, while those who adopted a mediated mode were more likely to be male, not an ethnic minority, and politically inactive. These particular variables appeared to cut across any broader cultural or national differences. Nevertheless, these associations did not meet the threshold for statistical validity normally required of quantitative research. Q methodology can pose significant limitations in this regard, particularly when such studies are conducted face to face, as the number of participants in a Q study is usually too small to permit identification of statistically valid relationships between viewing positions and other variables (Danielson, 2009). Furthermore, the results of a Q study cannot be generalized to the general population, as the P set is not representative of that population. Any findings are therefore specific to the sample of individuals studied. We will return to this issue later, as the question of external validity and generalizability of Q findings warrants further discussion. We would also note that there are various innovations currently occurring in online Q sorting and analysis of larger P sets that are likely to expand avenues for research that might well be able to generate statistically significant relationships between viewpoints and aspects of social location. This issue is also one we will address in greater detail below.

For those readers who are interested in how a Q study is written up, examples can be found in studies by Lindlof, Coyle, and Grodin (1998) on science fiction fans, Carlson and Trichtinger's (2001) study of responses to a racial incident in the television crime drama *Law and Order*, our own recent study (Davis & Vladica, 2010) which examines responses to an animated psychorealist documentary, and our *Avatar* reception project (Michelle et al., 2012). There have also been recent efforts to standardize and develop agreed procedures for conducting and reporting Q research, in an effort to enhance the validity of what is still a relatively new research method (see Dziopa & Ahern, 2011). In many studies, but not all, the written narratives that are constructed to represent each of the viewpoints identified through factor analysis incorporate some of the qualitative responses of those who loaded highly on each factor, as a way of illustrating the kinds of comments that tended to be made by group members in response to highly ranked Q items. As yet, there is no established process for selecting these comments. In our case, we sought to include remarks that best encapsulated or articulated the underlying sentiment that appeared to characterize that particular factor, or that illustrated most effectively a particular point that this group of respondents seemed to emphasize. For example, here is a brief excerpt from the analysis of Viewpoint 1 from our *Avatar* research, as reported in Michelle et al. (2012):

these viewers experienced intense emotional involvement with the characters and scenario depicted, and most strongly agreed with statement 26 (+4),¹ which expresses a sense of caring very deeply for the world of Pandora and its inhabitants:

First I was awestruck by the visuals, but soon became very attached to these characters and cared deeply for their well-being. I shed tears a few times and I don't normally for movies. (38-year-old Canadian man)

For some respondents' emotional response was unexpectedly strong and unprecedented:

This film reached me on a deep level, one that I cannot totally explain. (17-year-old American woman)

At first I was a little skeptical about Avatar, but after destruction of the Tree of Voices and then Home tree there were nothing but tears – and then *RAGE.* (20-year-old Russian man)

I could not stop thinking about this film after viewing it. It became very intense . . . I spent a great deal of time learning all I could about the film and even joined a forum, something I have never done. It moved me to see it 11 times in the theatre, no other film has done that. (38-year-old Canadian man)

Factor 1 respondents were so transported into the world of Pandora that they felt sad at the close of the film, and expressed a desire to become Na'vi (+3 on #32):

My life felt like nothing compared to being a Na'vi on Pandora. I fell into sort of a depression, like a lot (most) of the people on the Avatar-forums. (18-year-old Canadian man)

Here, we can see that the incorporation of qualitative data usefully illuminates and extends what would otherwise be rather dry reporting of aggregated findings, conveying little sense of the unique voices of individuals who nonetheless shared the same general subjective response to this film. It is this ability to convey something of each participant's individual perspective, as related in their own words, that some qualitative researchers perhaps fear losing through the reduction of rich expressions of human experience to quantitative factors. However, as we hope this example demonstrates, Q research can preserve at least some of that richness, while also offering a more systematic basis for the selection of qualitative data for inclusion – although such data obviously cannot take center stage. Further, while most Q studies present aggregated results, it is possible to focus intensively on individual responses to multiple Q sorts (Brown, 1993), or to examine prevalent viewpoints from the perspective of any particular individual participant, including those whose viewpoint may be regarded as of theoretical significance (for example, the author of a text), or even of individuals who do not load on any one factor, and thus have a very different perspective to any other participant.

What is Q Methodology's Potential Contribution to Answering Key Questions in Media Studies?

Q methodology is ideally suited to identifying commonalities as well as differences among the subjective perspectives, beliefs, experiences, and practices of different

groups of media producers, audiences, consumers, and users. This is, after all, precisely what the method was intended to do. But we believe Q methodology may also prove very useful in efforts to address, in particular, the link between media reception, consumption, and use, and the location of individuals within the wider social structure; something that it is not designed to do, but could help to do, when used in combination with other methods.

Most media researchers now take for granted that media reception, consumption, and use are social activities shaped by specific and diverse contexts. Because it is inherently social and contextual, it seems reasonable to assume that our engagement with media should also be patterned at the levels of social group membership(s), discursive affiliations, and personal and collective experiences, in ways that produce distinct groups of individuals who share certain similarities in terms of how they receive, engage with, and use media. In the field of audience reception studies, for instance, there is now a considerable body of research exploring this social patterning of interpretation and response (seminal work includes Liebes & Katz, 1990; Livingstone & Lunt, 1994; Morley, 1980; Press, 1989, 1991). However, because most audience research, at least in the cultural studies tradition, has relied on qualitative methodologies such as ethnographic observation, interviews, and focus groups and thus (with a few exceptions) been relatively small-scale, it has been very difficult to generate clear and generalizable evidence of the kinds of relationships that are theoretically assumed to exist.

In this respect, one of the most important potential contributions of Q methodology for media studies lies in the way it provides a robust foundation for linking shared subjectivity to aspects of social location in a methodologically rigorous and structured way. Q methodology has particular potential to help the researcher identify whether certain “types” of media audiences, consumers, or users share similar orientations or attitudes toward media products based on *actual* similarities in their responses, rather than any *preassigned* categorization of individuals determined by what the researcher assumes will be the most salient aspects of shared identity or group membership – as typically occurs in focus group research, for example. Using the responses to a separate questionnaire seeking information about aspects of respondents’ social location, sharing a generalized viewpoint can potentially be linked to other commonalities in terms of the sociodemographic characteristics, cultural competencies, experiences, and discursive affiliations of those who loaded on that factor. Furthermore, since identification of any common characteristics takes place “after the fact,” working backwards from the factor loadings to identify shared attributes between group members, it may be possible to isolate the particular aspects of identity, or the combination of social group memberships, that are linked to someone sharing a particular viewpoint or set of experiences with others. This process would provide a very robust and potentially fruitful means of establishing any correlations between social location and media consumption, reception, and use. For critical media scholars interested in exploring issues relating to media power and social inequality, a method of reliably identifying these kinds of correlations has thus far proven elusive. Q methodology, we believe, may be an important part of the solution to this problem.

There are various other advantages to using Q methodology, given the particular nature and strengths of this approach. Certainly, Q methodology's ability to map and systematically compare human subjectivities while preserving and apprehending the complexity of each individual's own multifaceted response is an advantage unmatched by existing quantitative approaches that seek to measure strength of association among variables or attributes. As Schröder and Kobbarnagel (2010, p. 123) suggest, the problem with quantitative questionnaires lies in "the atomized manner in which respondents answer the list of unrelated questions, thereby violating the coherences, interconnections, ambivalences and contradictions that are an inherent part of everyday life." While the semantic differential method does more directly address human subjectivity, it similarly does so "in an analytic, not a synthetic context" (Stephenson, 1985, p. 238).

At the same time, the fact that Q utilizes factor analysis allows it to circumvent one of the major shortcomings of much qualitative research, in terms of "the opacity of its interpretive procedures of analytical generalization" (Schröder & Kobbarnagel, 2010, p. 123; see also Schröder, 2011). While qualitative research can offer richly detailed insight into the subjective quality and content of specific encounters between media texts and audiences, consumers, and/or users, it can prove difficult to "reliably and validly generalize analytically" about similarities and differences within the very large and complex body of data that is often generated (Schröder & Kobbarnagel, 2010, p. 123). Q methodology, on the other hand, makes it "possible to incorporate and preserve qualitative data through a process of quantification" (Schröder, 1987, cited in Schröder & Kobbarnagel, 2010, p. 123).

A related issue pertains to the way in which the qualitative researcher, faced with often very large amounts of richly detailed data, must attempt to impose some kind of order and structure on the material, and normally develops or applies a schema according to which data is selected and categorized, depending on their intended focus. Some data, perhaps even a significant amount, is often left out or discarded in this process – as we ourselves have both experienced and witnessed in conducting, reviewing, and supervising numerous qualitative research projects. It is virtually impossible to include everything that may or may not be relevant, and as in all research, whether qualitative or quantitative, the researcher's subjective perspective on the topic shapes various aspects of the research process to some degree. In qualitative studies, one potential consequence of this inevitable subjective influence is a degree of uncertainty about whether the categories identified reflect "natural" and purely inductively derived, or rather partially subjectively constructed, distinctions among participants (Brown, 1996; Cross, 2005). The factors that arise from a Q study, on the other hand,

Exist as the consequence of a group of respondents having responded in the same fashion . . . The factor-categories are genuine, as opposed to ad hoc categorical, and reflect true attitudinal segmentation. They are more genuinely "operational definitions" of this-or-that attitude, since whatever they are definitions of . . . has been made

manifest by virtue of behavioral operations expressed through the medium of Q technique. (Brown & Ungs, 1970, p. 519)

Another key strength of Q methodology is that it is explicitly designed to preserve the integrity and richness of individual participants' subjective viewpoints, and because of this is perhaps less likely to produce findings that discount or minimize difference and diversity. Indeed, there are grounds to suggest Q methodology renders such diversity more visible and comprehensible in its full complexity (Stainton Rogers, 1995). Traditional quantitative surveys, for instance, are unable to capture subtle distinctions between the views of different participants; it is often very difficult to discern whether those who registered similar levels of agreement or disagreement with a particular item did so for the same reasons (Cross, 2005). With Q, it is possible to assess specific responses within the context of participants' broader subjective perspective, and to consider their response to one item in light of their responses to all others, as well as their qualitative explanatory responses, resulting in a more holistic interpretation. And while traditional qualitative methods such as focus groups, which are commonly used in media research, potentially allow for fulsome expressions of agreement and disagreement, practical difficulties arise when attempting to extensively probe all individuals to solicit more detailed and nuanced explanations of their own beliefs and opinions and then to construct rigorous comparisons between viewpoints. Nor it is easy to gauge and record individual responses to a constellation of related issues or questions *simultaneously*. On both counts, Q offers significant advantages over other methodological approaches.

One final key benefit relates to the potential applications of Q methodology for cross-national media research. An ongoing problem in qualitative research is the need to find a way to make more comparable observations that support stronger, testable generalizations that could potentially inform the development of theoretical understandings (Barker, 2006) of the nature of media production, reception, consumption, and use *per se*. It is particularly difficult to make linkages and generalizations across different qualitative studies conducted in relation to different texts and in different contexts (Schröder, 2011). However, with Q methodology, the standardization of methodological and analytical approaches potentially offers a unique means of addressing some of the challenges of cross-genre as well as cross-national comparative research, as identified by Livingstone (2003). This is because, as Schröder (2011, p. 22) argues,

its data are contextualized in the life worlds of the informants, that data can be translated into a standardized form, which makes it possible to perform common, standardized statistical procedures and to produce generalizations in the form of typologies that are transparent and immediately comparable.

Potentially, parallel multilingual Q samples could be constructed and administered relatively easily in FlashQ, and we are aware of one successful trilingual Q study.

Adapting and expanding the capacity of Q methodology in this way, it may become possible to “share and compare qualitative data across national contexts” (Schröder, 2011, p. 22). Given limited resources for the *Avatar* project, we were not able to undertake a large-scale cross-national study using multiple languages, but it became clear to us that such a study would be entirely feasible.

Hence, we are currently engaged in what we believe may be the largest Q study to date, which will draw together an international team of researchers to explore audience receptions of Peter Jackson’s feature film *The Hobbit: An Unexpected Journey* (2012), using parallel Q samples in multiple languages. In this project, we will delve much deeper into the potential of Q methodology to productively fuse the more nuanced interpretative detail generated through qualitative methods with robust quantitative techniques that make it possible to identify broader patterns within qualitative data, and to reveal meaningful correlations between individuals, shared viewpoints, sociodemographic variables, and aspects of social location. By using very large P sets (at least in Q terms – in the range of several hundred respondents), we believe it may be possible to construct smaller representative samples from a range of theoretically relevant categories or combinations of categories, and to produce typical Q sorts that represent any significant shared viewpoints we find. In this way, it may become possible to describe and compare the viewpoints of younger versus older viewers, of fans of the *Lord of the Rings* trilogy versus aficionados of J. R. R. Tolkien, and to explore patterns of response between and within different national or ethnic communities, religions, genders, and socioeconomic classes. While this is a very new area of exploration, we believe that innovative adaptations of Q methodology potentially offer critical media scholars analytical capacities beyond those normally derived through the use of qualitative or quantitative methods in isolation from each other.

For these and other reasons, we believe that Q methodology is particularly well suited to the study of media production, reception, consumption, and use. It also has considerable potential to expand the contribution, relevance, and generalizability of in-depth qualitative investigations, while informing larger-scale surveys and complementing close textual analyses with data relating to production, reception, or both. Proponents also emphasize the ability of Q methodology to test theoretical assumptions and make new and unanticipated discoveries through the use of factor analysis (Brown, 2006; Stephenson, 1995–1996). There are, however, some important limitations to this methodological approach.

Q methodology’s primary focus is on identifying and interpreting the subjective viewpoints and experiences of nonrandomly sampled participants, and it is commonly regarded as an exploratory, interpretation-intensive methodology that is primarily suitable for use with quite small numbers of respondents (Brown, 1996; Cross, 2005). On its own, Q methodology cannot be used to identify statistically significant causal relations between viewpoints and other variables; nor can the findings of a Q study be generalized to estimate the distribution of the identified perspectives within the wider population, as it does not use statistically representative P samples (Dziopa

& Ahern, 2011; McKeown & Thomas, 1988; Stainton Rogers, 1995). In order to examine the distribution of subjective viewpoints within the general population and their possible link to sociodemographic or other attributes, it would be necessary to use the results of a clearly defined and robust Q study as the basis for a larger-scale representative survey in which random sampling is used.

This can be achieved in a few different ways, for instance through the creation of Likert items based on the distinguishing elements associated with each factor, which could then be used to measure the prevalence of perspectives within the wider population (Danielson, 2009). Alternatively, the researcher could use the method of narrative evaluation, where the factors identified through a Q study are transformed into short narratives that a representative sample are asked to rank and respond to in terms of their level of agreement or disagreement (Danielson, 2009). A representative survey based on a preliminary Q study would make it possible to both ascertain the external validity of the identified viewpoints, and *independently* link viewpoints to variables such as culture, ethnicity, gender, age, socioeconomic class, education, religion, and political belief, thereby addressing a key area of ongoing research and debate within media studies. Q methodology could thus form a key component of mixed methods research, perhaps serving as an essential bridging or translation device between in-depth qualitative interviews and survey research, in a way that makes it possible to combine qualitative and quantitative methods more productively.

One additional problem relates to what Schröder and Kobbernagel (2010) refer to as the “validity cost” that arises from the participants having to reduce their complex and multifaceted discursive response to forced choices in the ranking of Q items, the selection of which, some contend, is open to subjective biases and also potentially limits or predetermines the range of possible responses that can be expressed (see also Cross, 2005; Dziopa & Ahern, 2011; Stainton Rogers, 1995). While this is true to a certain extent, the process of questioning participants about their selections can potentially offer insight into themes or topics that are not explicitly addressed in the available Q items. Another issue arises in that since the interpretation of the factors relies on the researcher’s own analytical skills, existing understandings, and intuition, there is a potential risk of subjective biases at this stage, particularly when the researcher seeks to draw conclusions about the data (Cross, 2005; Stainton Rogers, 1995). This particular concern is not, however, specific to Q methodology, and is a problem that may arise in the interpretation of even purely quantitative data.

Conclusion

In sum, Q methodology offers considerable but still largely unrealized potential for media studies, and is particularly suited to research aimed at uncovering broad patterns, similarities, and differences in the subjective perspectives and experiences of media producers, audiences, consumers, and users. Q methodology may also have

potential utility for testing general propositions about the nature and form of media engagement, consumption, and produsage. Certainly, our own research suggests Q offers considerable insight into specific areas of commonality and divergence within the receptions of audience members located in diverse national and cultural contexts; it also provides more robust insight into the likely basis for such variations in audience engagement and response, and clarifies pathways for future research. Q methodology is unparalleled in terms of its capacity to systematically identify and describe similarities and variations in human subjective viewpoints. Recent technological developments in terms of online Q sorting and computational software also make this method accessible to increasingly fragmented and dispersed media audiences and users, as well as to researchers who would otherwise not consider using a qualitative research approach “fortified” by factor analysis. Indeed, it seems that a method such as Q, which is adaptable to an online environment when warranted and which draws on the strengths of both qualitative and quantitative traditions, offers significant promise in terms of enabling emerging scholars to grapple more effectively with the complexities of media production, reception, consumption, and produsage in an increasingly convergent and pervasive digital media age.

NOTE

- 1 As shown in Figure 4.1, “+4” refers to the aggregate ranking given to this statement by this group of respondents, who “most strongly” agreed with the sentiment it expressed.

The Interview

A Process of Qualitative Inquiry

Sue Robinson

ABSTRACT

The interview in qualitative inquiry extends to surveying, one-on-one in-depth investigation, impromptu ethnographic meetings, formal focus groups, and free-form dialogue, depending on the nature of the research puzzle. Researchers have called interviewing “an unfolding interpersonal drama,” “a marriage with hidden truths,” “a narrative practice,” and “an unfolding story.” At its heart, the interview entails an investigation into individual motivations, interpersonal and communal relationships, life engagement, as well as civic, familial, and other kinds of problems and resolutions. The interview’s execution is both art and science, with the end result an unveiling of meaning construction, information processing, and knowledge documentation. This chapter describes the dynamics of the interview, including guidelines for building question templates (or not), navigating university institutional review boards, accessing informants, collecting the information, and then analyzing the data.

Interviewing as a mode of qualitative inquiry can unveil the process of meaning construction, the dynamics of relationships, and the formation of knowledge – if executed effectively. Called “the gold standard of qualitative research” (Silverman, 2000, pp. 291–292), the methodological technique must be approached as both a creative, malleable art form and a scientific technique that produces data. Sola Pool (1957, p. 193) called the interview “an unfolding interpersonal drama with a developing plot.” Two leaders in qualitative scholarship, Thomas Lindlof and Bryan Taylor (2002, p. 173), describe the interview as the act of soliciting people’s stories. Gubrium and Holstein (1998) go further with the storytelling metaphor, likening the interview to the plot and regarding the interviewer as author *and* character. In my favorite comparison, Oakley (1981, p. 41) considered the interview as a marriage: “everybody knows what it is, an awful lot of people do it, and yet behind each closed front door there is a world of secrets.”

This chapter aims to open any closed doors to interviewing and to reveal the secrets that lie within the method. It begins with a nod to the long history that interviewing as a research method in the social sciences has accumulated before articulating a philosophy and typology of interviewing as a way to approach empirical truth seeking. Essentially, the chapter seeks to celebrate the multiple dynamics of the interview, which represents a powerful methodological tool. It is particularly well suited to studying the power and influential relationships that people have with media – the topic of this chapter. The bulk of this chapter will lay out a pragmatic guide for students of qualitative interviewing, providing practical suggestions for developing questions, drawing a sample, undergoing institutional review board interview protocols, and collecting and analyzing data. It takes as its thesis the idea that every interview exercises a power relationship in and of itself, inasmuch as it is meant to reveal power relationships. And every researcher must carefully consider the type, style, technique, tone, mode, and execution of the method in conjunction with the targeted population as well as the overall research goals.

Interviewing: A Brief History and Philosophy

From its roots, interviewing has been linked to ethnography as a way to study human conditions, cultures, and communities (Vidich & Lyman, 2003). Two early pioneers of the development of the interview method, Henry Mayhew in the 1860s and Charles Booth in the 1880s, spent time with the poor people of London in the United Kingdom and published accounts of their lives through surveys, unstructured interviews, and ethnographic observations. In approaching the people as capable of representing themselves and competent to explain their life experience, these two revolutionized the field of sociology and launched interviewing as a valid method (Converse, 1987). Furthermore, through this triangulation of qualitative data, these ethnographers established the interview data collection method as one that depended on observation as much as question protocol.

Throughout the 1900s, particularly in the United States, such as in the Chicago School, scholars turned to the interview as a key technique to understand notions such as psychological measurement, the “Other” via American exclusion, community adaptation, and opinion polling (Fontana & Prokos, 2007; Maccoby & Maccoby,

1954). By the 1960s, about 90% of data in the two top American sociological journals came from interviews and questionnaires (Brenner, 1981). From formal polling of populations to informal conversational exchange, early interviewing in qualitative work had creative, anecdotal, interpretive qualities that contrasted with post-World War II attempts to use the survey as an instrument to quantify data. Throughout the twentieth century, interviewing became more ubiquitous in all fields, including media and communication studies (Fontana & Prokos, 2007). During this period, from the 1950s through the 1960s and 1970s, the schism between qualitative and quantitative interviewing and surveying of people widened, not only in terms of how samples were drawn and data was collected via questions and items but also in the coding and analysis of the resulting transcripts (Fontana & Prokos, 2007). In the end, however, all of these scholars – quantitative and qualitative – were querying people to find out something important about society.

So much of what we read about interviewing – its dimensions, its applications, its strategies – is framed according to power and power relationships: Who shall wield the power in the interview? How shall the power manifest, and to what end? Denzin (1978) considers interview talk to be for someone else's benefit and acknowledges that inevitably one person in any conversation must exert greater control than the other(s). Ithiel de Sola Pool (1957) wrote:

The social milieu in which communication takes place [during the interview] modifies not only what a person dares to say but also even what he thinks he chooses to say. And these variations in expression cannot be viewed as mere deviations from some underlying "true" opinion, for there is no neutral, non-social, uninfluenced situation to provide that baseline. (p. 192)

Indeed, he pointed out that the dynamic contingencies of the interview itself activate opinion; even presumed knowledge extracted can be no more than the manifestation of the interview interaction (Cicourel, 1964). "Each interview context is one of interaction and relation; the result is as much a product of this social dynamic as it is a product of accurate accounts and replies" (Fontana & Frey, 2008, p. 64). Fontana and Frey went on to describe the interview as "an active, emergent process" (p. 76), but I would ask: Who leads that process and who submits? And, more importantly, why? Do the resulting power dynamics innate in the technique itself influence the data outcome? If we accept that the interview itself is a "social encounter," as Holstein and Gubrium (1995, p. 3) do in their advocacy of an "active approach" to interviewing, we must understand that the interview interaction itself must bias any derived data.¹ Because every interview involves a communicative exchange of more than one person and because none of us can read minds, every question *and* every answer hold the possibility of misinterpretation, nuance, and mistaken emphasis. It is the responsibility of the researcher to parse out what is really going on as much as possible. This fundamental reality shall be present at every stage of the methodological process – from beginning to end.

The question of power is an important one whenever an interview protocol is developed. The effect of a male interviewing a female, a youth interviewing an elder, a White person interviewing a minority ethnic person can sometimes arise in validity concerns: Is the participant articulating a response based on a reaction to the interviewer or was her response true to her internal processing? Therefore, the understanding of those power dynamics must be incorporated into the context of the answers, but also into the very approach of the interview and the protocol. Complete background and demographical information about the informant must be collected, even as the personal history must not trump any contemporary meaning discussion. Approaching the interview data later on from a dialogic perspective will adapt the frame so that any power influence can be considered as one version toward the truth; that version is just as interesting as any other “real” answer, had the interviewer been Black or old or female. It is essential that the context of the information exchange be documented and analyzed accordingly. “Any transcription of speech must be understood as a compromise” (Elliott, 2005, p. 51).

This power question is also relevant at the beginning of the interview process, when the sample is determined: Who will be privileged to speak? Students often ask how many people they must interview to achieve methodological saturation, and I respond that this is the wrong question. Rather, they should be asking, “Who in my target population or community must share information if I am to understand this research puzzle?” The answer to that first question will be answered with the response to the second. If one is interested in power dynamics within an information producing community, for example, the researcher cannot limit the sample to the leaders of that organization, but must understand the perceptions of the reporters as well. Yet it must be considered that for every person allowed to speak, many others will be absent from the data collection. One cannot interview everyone.

These articulations of the epistemological nature of interviewing are important in delineating one’s ultimate goals in the interview: collecting themes, deciphering motivations, and exploring concepts and dimensions in order to say something larger about some societal phenomena in the understanding of ongoing social practices. Lofland and Lofland (1995, p. 16) argued that in order to develop social theory: “(1) face-to-face interaction is the fullest condition of participating in the mind of another human being, and (2) . . . You must participate in the mind of another human being . . . to acquire societal knowledge.” Researchers must work to “enter the mind” of participants and informants in order to extract the knowledge and information around a particular topic of inquiry. Asking enough of the right kinds of questions will help to access the truth of the person (and to help the persons themselves know that truth). “Respondent interviews are a lens for viewing the interaction of an individual’s internal states (social attitudes and motives) with the outer environment. The interview response is treated as a ‘report’ of that interaction” (Lindlof & Taylor, 2002, p. 175).

Interviews help us document and “know” historical events, societal tragedies, and triumphs, outcomes, predictions, and trends as well as allow us to understand how

we live, who we are, and what we need for life fulfillment. In terms of media study, interviews can shed light on all of these experiences, situations, and relationships at all levels of production, the site of content and consumption. Examples of some research questions that interviews might illuminate include: How are digital technologies changing our perceptions of mediated time and space? How have concepts of “news” changed over time? How is Twitter changing power hierarchies in our society? How does childhood memory of the news coverage around national traumatic events influence our relationships with our children today? In-depth interviews that allow a participant to respond in context provide a rich documentation of these societal quagmires.

Once these questions of goal and sample are solidified, the interviewer can begin to make decisions about the kind of interviewing and analysis that need to take place. The remainder of this chapter explains how to exercise different approaches to interviewing in a pragmatic way.

Kinds of Interviews

First, the interviewer chooses the interview tool: What type of interview is called for? The method and style of the interview follow the research questions, with consideration of the target population involved as well as the researchers’ own limitations – resources, personality, and other constraints. Scholars of all disciplines have spent a lot of time classifying kinds of interviews according to how formal and standardized the interview template is, whether the response goal is measurement, and the amount of freedom the participant maintains (Holstein & Gubrium, 1995; Maccoby & Maccoby, 1954; Madge, 1965). Moser (1958) developed a continuum for interviewing that is a useful way to think about the types (as cited in Holstein & Gubrium, 1995; see Figure 5.1).

Figure 5.1 Functional interview continuum (adapted from Moser, 1958)

With Moser's adapted scaled typology as a guide, I shall explicate the interview types according to the level of control (or power) the interviewer exerts.

Active/Free

At the far end of the continuum, we have the "active" and "free" interview styles. Jack Douglas (1985) calls free-form techniques "creative interviewing." This style of interviewing encourages the exploration of identity boundaries, of cognitive processing, of creative expression, of oral history, and other kinds of qualitative responding. "Interviews allow us to hear, if we will, the particular meanings of a language that both women and men use but that each translates differently" (Anderson & Jack, 1998, p. 65). No interview template is used; the subject and the interviewer simply talk. This style depends upon a rapport between researcher and participant, which must be built within the conversation. In this category we might also include the ethnographic interview (Lindlof & Taylor, 2002), the informal conversational interview (Patton, 1990) and the situational conversation (Schatzman & Strauss, 1973, p. 71) that can occur in the field. At this end of the continuum, the researcher and the participant share power equally for the direction of the interview.

Focus Groups

Both formal and informal, the group interview gathers a multitude of people to discuss a specific topic, text, problem, query, or phenomenon. Focus groups depend on a well-trained, directive moderator to help prevent groupthink, encourage all members to participate, keep the discussion on track, and otherwise insure the collecting of useful data (Fontana & Frey, 2008). Group interviews can be particularly useful when studying relational aspects of mediated engagement. Via group interviews, one can witness literal, real-time communicative processing as well as the hierarchal positioning that happens around some topics when discussed socially. Watching the power dynamics that arise in such interactions can be useful and fascinating.

Structured and Semi-Structured Interviews

These tend to be for one-on-one or with pairs of subjects. The "structure" of this refers to how strict the researcher needs to be with the protocol of questions. A structured template is one in which the researcher has a set of questions that must be asked, in the order laid out. This would be for those projects that need a more uniform response from participants. The much more ubiquitous semi-structured form provides a guide template for the researcher that allows for a more conversa-

tional approach to the exchange. Lindlof and Taylor (2002, p. 179) call this a “narrative” interview that results in a “dyadic interaction.”

Open/Closed Surveys

The use of open or closed surveying helps a sample clarify concepts, break down opinions, determine motivations, categorize attitudes, and also understand how people interpret their own motivations (Lazarsfeld, 1944). It is important to remember that the general survey represents people’s perceptions as opposed to their actualities. The closed survey – that is, one where the items are close-ended or scaled – and the open survey where open-ended questions are employed both have the problem of self-reporting bias but can document important attitudes and habits; the survey is particularly popular among social sciences studying media.

Controlled

The most stringent of structured interviewing is called the “controlled” interview. Moser (1958, cited in Holstein & Gubrium, 1995) described this as an “interrogation.” He likened this style of interviewing to a police interview where the end objective is to derive a very specific answer.

Power concerns come into play at this stage of the design process as well, for how the template is structured and what style of technique is selected will determine the nature of the responses. As Camitta (1990, p. 26) wrote: “The interview, as a social genre that is controlled by the interviewer, is a form of mastery over object, acquisition of knowledge through control of language. Conversation, on the other hand, is more collaborative, depending upon affiliation rather than upon separation in its structure.”

Thus, the choice of interview style will be based on the research questions to be explored. For instance, a researcher interested in understanding a topic deeply but specifically might opt for some kind of one-on-one semi-structured interview style. Someone seeking to investigate relationships or identity might find the opportunity to witness the exchange of dialogue and information within a focus group particularly worthwhile. Ultimately, even the most free-form of interviewing must yield some kind of specificity for the researcher (otherwise, what’s the point?) and the most controlling of styles will inevitably veer off script.

Institutional Review Board Approval

Once the study has been designed, the onerous process of the university institutional review board (IRB) must be navigated. This section relates most specifically to the

research process within academic institutions in the United States, even though similar processes of organizational oversight certainly exist in other contexts and cultural environments. Many wring their hands and complain about IRBs across the nation, for the bureaucracy increased as institutions sought to protect study subjects and limit the liability when studies go bad. However, the training programs IRBs offer (or mandate) provide a useful opportunity, for budding and more advanced researchers alike, to reflect on the ethics of research.

The most important aspect of this process is to be as detailed as possible in answering the protocol questions without constraining future modifications (such as adding questions or even topics) to the study design. For example, researchers might consider increasing the anticipated number of study participants by about a third to allow for flexibility later on. The protocol offers a chance to consider whether or not you will identify your subjects and also whether you will deceive them: these will be key elements in the protocol approval. Many interview participants in media studies are not identified and not deceived (except in surveys that pair with experiments, but that is not the purview of this chapter). Most IRBs will want a viable confidentiality process for those participants, including a method for protecting and disposing of the transcripts and recordings collected. For those who wish to identify the participants, IRB will want to know the reason and be reassured that the information will not damage the person's reputation, livelihood, or life in any way. One alternative might be to name the person's organization – for example the *New York Times* – without identifying that person by name.

Some other tips related to the IRB process:

- The IRB process may take months. Beginning the process as soon as possible will help keep the data collection on schedule. Most IRBs post their meeting schedules and deadline on their websites.
- The administrator of the protocols can often be a great resource for understanding the best way to craft a successful protocol.
- Much can be gained from having an experienced person within the specific IRB look over the protocol before submission.
- Some universities will provide successful IRB protocols or samples of applications for researchers to model.
- At some schools, different boards (e.g., for education, social sciences, for medicine, etc.) govern different topics. For example, if you are studying how children communicate in schools, you might consider asking the educational division for a review of your protocol rather than your typical social science committee, as the education IRB would deal more frequently with research relating to children.
- Any future modifications to the study will require modifications to the protocol as well. Anticipating as many of those changes (such as more interviews with different populations, in different places, or with different questions) in the original protocol will save time later.

- Generally, any co-principal investigators and key personnel must have undergone any IRB training, which can take time.
- Often IRBs will offer different types of review, such as exempted, expedited, and full reviews. Exempted usually means the research involves information in the public realms, uses existing data, or otherwise offers minimal risk and does not need review by the board. Expedited reviews are typically for minor modifications or renewals of existing protocols or for those projects posing minimal risk. Everything else that involves interview subjects must usually go to full reviews in the academic settings. For example, my request to interview journalists about their attitudes on blogging was expedited because those comments are pretty formal in nature and don't pose any risk to journalists talking about this public realm issue. However, my protocol asking journalists about their news organization and attitudes about their jobs needed a full review because the board determined there was risk that the reporter as an employee might get into trouble with their bosses and so they wanted to insure proper confidentiality measures were in place.

Often scholars will be asked to answer questions, submit additional documentation, and make revisions during this process, which can take anywhere from a couple of weeks to months. It is important to keep in mind that IRB approval generally lasts for only a year and needs to be renewed and modified as the research develops. Also, because IRB members often cycle off in 1–3 years (depending on the university), researchers must periodically get reacquainted with the composition and particular philosophy of a new board.

Drawing a Sample

As we exist in “the interview society” (Silverman, 1993), researchers have the benefit of populations familiar not only with viewing interviews in the media but, most likely, with having been interviewed themselves. Yet, as with all the other aspects of the study design, the selection of the sample must be undertaken with care. Unlike quantitative surveys where the goal is to find as generalizable a sample of a particular population as possible, the qualitative in-depth interview must tap participants who will yield rich, thick responses that delve deep into some topic. As mentioned earlier, those who are privileged to speak hold great power to influence the resulting research and implications of the findings.

The selection of interview participants depends entirely on the ontological nature of the study, the proposed research questions, and the kind of method and style of interrogation chosen. For example, sampling can be “provisional,” “tentative,” and “spontaneous” in ethnography (Glaser & Strauss, 1967/2009), which means that a researcher chooses participants according to the flow of the ethnographic encounter

and not according to some rigid typology. For structured templates that seek to draw out the very specific situated knowledge of a particular group, the sample must be targeted and focused. Each person's capacity for answering the questions honestly and thoroughly must be weighed during the sample selection (Mason, 2002). This is not to say that people who might be inarticulate or otherwise need help to understand how they want to answer should be excluded, only that those possibilities should be considered when choosing whom to interview, the length of time needed for the interview, and the structure of the questions.

Other notes on sampling:

- How many people is “enough”? I have seen viable studies that interrogated just a handful of people and then others with hundreds. Generally speaking, studies need enough people to achieve saturation (that is, the point at which you know what the person is going to say before they say it because you have heard it from enough other people). Research questions should guide the sample. For example, if your question has to do with how female publishers deal with gender power dynamics in the news industry, you could interview just a handful of women publishers because so few of them exist. However, if you want to know how reporters investigate politics, then you would want to talk to as many political reporters as you can – I would suggest at least a dozen, but 25 or more would be ideal. Expect the interview to take 30 minutes to two hours. The optimal size for a focus group is 6–12 people, and each session tends to be about 90 minutes in length (Lindlof & Taylor, 2002, p. 182).
- Recruitment strategies determine the composition of the sample. If, say, you want a general population in a local town, then you will want to attract people in a variety of methods: not just by taking an ad out in the local paper or media organizations (which will garner older, educated, middle-class adults) but also by soliciting people in public spaces such as parks or farmers' markets and via the snowball technique (asking subjects for other names), and by appealing to community and school listserves, among other places.
- Lofland and Lofland (1995) recommend that researchers sample from a population that they themselves are part of, that is, “starting where you are.” If you have a hobby or interest in a particular area, Lofland and Lofland suggest you draw upon that background of knowledge. For example, if a researcher has been a reporter or producer in the past, he or she could refer to that content production lexicon or use network techniques from that industry when interviewing that population. This could allow for better access and gain greater trust from informants.
- Offering incentives for research participation can encourage a more inclusive sample. For example, students often receive credit for courses. Other popular rewards include payment, reimbursement of mileage, coffee or lunch, and entry into a raffle for some prize.

- Soliciting subjects and gathering contact information at events is a great way to draw a sample (though interviewing people at the event for research purposes raises problems of sound and distraction).
- The parameters of the interview, such as length and confidentiality, should be clearly communicated. The last thing a researcher wants is to promise a 20 minute meeting, knowing the interview will take an hour, and then have the subject leave.

Developing Questions

Interviewing is about being aware that “(1) actions, things and events are accompanied by subjective emotional experience that gives them meaning; (2) some of the feelings uncovered may exceed the boundaries of acceptable or expected female behavior; and (3) individuals can and must explain what they mean in their own terms” (Anderson & Jack, 1998, p. 169). These researchers were discussing gender issues within interviewing, but the point can be generalized. The interview template should help the subject access those perceptions and experiences in an articulate manner. Most researchers agree that interviewing involves “the construction or reconstruction of knowledge more than the excavation of it” (Mason, 2002). They suggest that every interview is a representation of an interaction between interviewer and interviewee as well as about the pure gathering of information. With this in mind, question development for the interview should be a flexible act that can morph not only from participant to participant but also within the interview itself. The interview could be considered as a living thing that can be quelled or propelled forward with just the right question – or even just the right amount of silence or subtle gesture. And yet, though the goal of every interview will always be to record a “dynamic unfolding of the subject’s viewpoint” (Anderson & Jack, 1998, p. 169), the interview process must always be activated within the context of the ultimate aim of the research: How do I ask questions so I have the necessary information to answer my research questions? I like to think of my template as keeping the subjects on a narrative course that unveils situated knowledge in an ordered manner.

Often my students complain that their interview participants declined to fully answer their questions, responded in monosyllables, or otherwise provided only superficial information. They were not getting “anything good”! The tone and the framing of every question matters as well as the order in which it is asked (Anderson & Jack, 1998). Even facial expression and body language will change how a person answers, in addition to what the conversation was like before the question was posed. If you change the topic with a new question too early in a person’s recounting, you set boundaries for the interviewee, who will limit or expand on his or her next answer accordingly. The respondents’ past experiences, position, gender, race, age, and so on should be considered when selecting question strategies. Each template might

incorporate a variety of strategies, such as nondirective (“Describe your experiences . . .”), directive (“Please compare X to Y”), the use of a common lexicon, requests for anecdotes and examples, and the posing of hypotheticals. The right tone and question structure will depend on the situation, the participant (and the participant’s experience), and how specific you need them to be. Statement making on the part of the interviewer can be off-putting. Gender and race can cause people to enter the conversation with predetermined judgments about your motivations. Allowing extra time at the beginning of the interview can help participants feel at ease about your intentions.

Other tips include the following:

- Follow-up questions are key to arriving at a complete answer. Most people will not understand the full dynamics or implications of the posed question, or they will use the first response to “work out” what they really want to say.
- When asking questions, the interviewer might refer to current events and situations as a way to demonstrate appropriate knowledge of the background and context. This helps build credibility with participants.
- Recorded pre-interviews can cue the researcher to being alert to leading questions and an aggressive tone.
- Jargon, loaded terms, or academic language in questions can confuse participants.
- Allow silence to encourage elaboration.
- Many of my participants ask me for a list of the questions I am going to give them. I provide them with a generalized template but resist giving them an entire blueprint. I stress to them that the interview will range and that I will follow up on their answers. Still, being able to contemplate their answers makes some people feel less nervous, and I accommodate them as far as my research purpose allows.

Collecting the Data

Data collection entails the interview itself, which can last anywhere from half an hour to several hours, as well as the filing of the audio recording and the transcript. I begin each interview by informally chatting and then discussing the study and what I am hoping to accomplish. I always stress the applied research part of my intention, as people like to feel that they are contributing to a greater cause. We generally have a conversation that I do not record about some topic that is similar to but not exactly like the interview itself as a kind of warm-up. I buy them coffee and let them get settled. I give them an opportunity to get used to whatever recording devices I have on the table. I explain to them that I want them to be completely honest with me and to let me know if something I am asking makes them uncomfortable. I talk to

them about how they can end the interview at any moment and can withdraw their participation at any time, even after the interview has been completed. I can see them visibly relax when I say this.

The modes of interviewing I use include face-to-face interviews (either group or individual), phone, letters, Skype, iChat, and email. Each has its benefits and negatives. I prefer face-to-face interviews because I can see immediately how the person is reacting to my question, tone, gestures, and so on. I have also used phone chats, which work well because the person is somewhere they are quite comfortable and does not see my recording devices; they can often forget that it is a researcher on the other end. Also phone interviews allow me to contact people who may not live near me. Skype and iChats are similar to phone interviews (though Skype especially can be glitchy). Bird (2003) elected to interview via both letters/email and phone, though both methods have been criticized as being ineffective, abbreviated, and lacking in intimacy (Babbie, 1989; Bird, 2003; Chadwick, Bahr, & Albrecht, 1984). Rather, Bird found intriguing differences: where women wrote long, emotional letters to her questions and spoke intimately on the phone, men kept their responses in both media more brief and businesslike. She wrote of her methodological experience:

I am not suggesting some kind of blanket advocacy of phone interviews or letters for women . . . Businesswomen who use the phone all day at work may not relish the thought of a long phone interview. Those who write a lot at work may see writing letters as a chore, while those who have literacy problems might view a request to write as a threat or embarrassment . . . All methodological approaches are characterized by constraints; the key is to be flexible . . . and be aware of the possible impact of methodological choices. (Bird, 2003, p. 15)

She and other researchers suggested that the particular mode of communication will affect the power dynamics innate in the exchange of data. For example, a phone interview will mitigate some of the power dynamics by removing the social pressure of appearance (Bird, 2003, p. 15). In contrast, I have found that in email interviews (which all my students are eager to do), participants take advantage of the absence of that social pressure and dominate the exchange such that the researcher may not achieve the saturation he or she desires. In effect, the researcher *loses* power (and that's not good either). Email responses are often truncated and superficial, follow-ups are difficult to enact, and difficult questions are sometimes skipped altogether.

When the interview has commenced, the researcher must not only record the voice, ask the questions, and take notes, but also observe what Gorden (1980, p. 335) describes as four modes of nonverbal techniques: proxemics (use of interpersonal space to communicate attitudes), chronemics (the use of pacing of speech and silence), kinesics (body movements or postures), and the paralinguistic (variations in tone, pitch and quality of voice). The interaction, understood and considered in a holistic manner, must be noted and analyzed (Anderson & Jack, 1998).

Indeed, social convention binds all of our interview participants, each of whom embodies multifarious life experiences that color all their responses (Anderson & Jack, 1998). In other words, is the woman speaking as the daughter of someone who spent every morning sharing the newspaper at the breakfast table (e.g., tinged with the interpersonal experience of the mother–daughter relationship) or as a mother herself (thinking of her desire for her own children to be informed citizens)? She activates different parts of her experience depending on her mood (as well as what happened most recently, e.g., a good day, a fight). Furthermore, those life experiences will leak into all of her responses and form a reaction to you, your gender, your dress, and your body language. For example, a woman will respond to a male interviewer differently from a female one as “gender filters knowledge” (Denzin, 1989, p. 116). Similarly, participants must be allowed to switch voices (i.e., they might move out of the category to which you have assigned them) and also contradict themselves. I find that my participants sometimes like to “try out” an answer before giving their real response.

One strategy for beginning to organize the prolific amounts of data the project will generate is what I will call a “pre-memo.” A pre-memo is essentially a series of comments that the researcher makes while reviewing the interview transcript immediately after the data collection. I say *after* the data collection, but I really consider this to be part of the data collection because this pre-memoing should occur in conjunction with the interview itself. The pre-memo is not the same thing as a formal “memo” in the Strauss and Corbin grounded theory tradition (see the next section for more on that). Rather it is a chance for the interviewer to make a note of all the gesturing and emphases the participant imparted that were not recorded and a chance to make more general observations about what was said. For example, a pre-memo might include notes about how to ask the question differently the next time or a reminder that another interview subject has said something similar. I am very informal in these pre-memos, as they are only for my eyes. I will often comment upon what I have heard, its credibility, for example, or its resonance with what others have said or simply add context to whatever was said, such as “Her comments on the media coverage here came the day after a big controversy involving a local reporter and the campaign.” Knowing I will be doing pre-memos helps me to put aside the process of analyzing during the process of listening (Anderson & Jack, 1998).

Other notes on collecting data include:

- First and foremost, the interview participant should sign the informed consent form with the IRB approval mark, if one needs to be completed.
- Where the interview takes place matters: a loud coffee shop or the person’s home? In part, this depends on what will be discussed: sensitive material is probably best exchanged in a more private place.
- Audio recordings of interviews – with transcription – provide the evidence and must be made in order to have a record of the data. I recommend taking notes

as well. I like to use my laptop, but some subjects will feel uncomfortable with a machine between you and them. The computer and the tapping of the keys interrupt the interchange, and thus the intimacy. If you are interviewing in person, you can usually tell right away if the interviewee is distracted by your recording devices based on his or her furtive glances at the machine and halting answers. I suggest using a banana-clip lavalier as a microphone and then moving the recorder to your bag. Another option is use your mobile phone as a recording device, which can be less obtrusive for some people.

- Pre-interviewing for demographic data can save time. The person's age, income, education, and other information will allow for a comprehensive characterization of the sample in the methods sections later on.
- Signs of confusion, reluctance, ambiguity, and contradiction should all be noted in context. Silence might indicate interesting intersections between culture, ideology, and social roles (or it could just mean they are choking on a cookie).
- Follow-up questions should not shut down the flow of the conversation.
- If the person suddenly tells you he or she must leave early, skip immediately to the most important questions and ask if you can either meet again or send follow-up questions in an email.
- Sometimes my participants will ask to see any article before publication. I tend to acquiesce. If the person wants to change his or her comment, I consider that to be an important action; often the desire to self-censor is an important data point. This is, after all, not journalism. The main goal here is to make sure the person's thoughts and perceptions are taken down accurately. Occasionally a researcher's subject matter or a person's desire to completely change what was said will make this an awkward request. At that point, the researcher may consider dropping the participant from the study or negotiating the meaning of the evidence until he or she is appeased.
- It is best to avoid applying existing schema and biases to what you might hear.

Analyzing and Writing the Data

The words of the participants in the interview project represent the units of analysis. The researcher should have an analytical tool in mind as he or she approaches this raw data. First, he or she must consider which analytical technique makes the most sense: a deductive approach such as grounded theory, or an inductive approach such as a specific theoretical framework. Discourse analytic techniques will enable a researcher to explicate how knowledge concerning the topic at hand is narratively constructed (see Fairclough, 2003; van Dijk, 1985, 1993). Discourse analysis is particularly useful because it can help uncover the power, social, cultural, and other relationships at work in the person's construction of dialogue. As the researcher sets out to analyze the interview transcripts, he or she must explore three significant

relationships within the text, according to Anderson and Jack (1998): (1) the linguistic or performative aspects of an interview; (2) the individual connectors; and (3) the interview data as situated in a social historical consciousness. This is done by: “(1) listening to the narrator’s moral language; (2) attending to the meta-statements; [and] (3) observing the logic of the narrative” (Anderson & Jack, 1998, p. 169). The “moral language” refers to the participant’s value system as revealed by the choices of phrasing and other dialogic classifications that indicate a person’s identity paradigm.

Meta-statements alert us to the individual’s awareness of a discrepancy within the self – or between what is expected and what is said. They inform the interviewer about what categories the individual is using to monitor her thoughts, and allow observation about how the person socializes her feelings or thoughts according to certain norms. (Anderson & Jack, 1998, p. 168)

The final key in any analytical experience is to discover the patterns, recurring themes, and narrative links among this moral language and the metastatements – or “observing the logic of the narrative.” The connections made during this exploration of the “narrative logic” will reveal the underlying meaning in relation to theory. This process is the essence of discourse analysis but is also very similar to grounded theory analysis as described by Strauss and Corbin (1998).² For Strauss and Corbin, the researcher conducts a three-pronged analysis called open, axial, and selective coding. Open coding involves the initial read through of the text that identifies general concepts, their properties and dimensions. In axial coding, the researcher reviews the texts again with the concepts to link categories and reveal thematic patterns between the concepts. Finally, selective coding helps a researcher establish the theoretical implications for the patterns discovered.

Every person’s context and experience must be considered as an analysis unfolds. This can be done in the analytical “memo” and diagram, which Strauss and Corbin (1990) insist upon.

Writing theoretical memos is an integral part of doing grounded theory. Since the analyst cannot readily keep track of all the categories, properties, hypotheses, and generative questions that evolve from the analytical process, there must be a system for doing so. The use of memos constitutes such a system. Memos are not simply “ideas.” They are involved in the formulation and revision of theory during the research process. (Strauss & Corbin, 1990, p. 10)

I am a big believer in the analytical memo (text) and diagram (which is basically a visual memo) as it forces the researcher to engage actively with the material, to find connections that might have been missed through a mere interpretive analysis, and to think more conceptually about the data.³ The written memo can consist of a comment next to a piece of evidence (i.e., the participant’s words) as short as a word

or phrase such as the name of a emergent theme (“connotes freedom of the press”) or a theoretical note as long as an essay. I often draw directly from my memos for my resulting papers, and thus consider this process a form of draft writing. The diagram can help formulate the connection between concepts in a more structured manner, but can also depict the relationships or flow or directionality being revealed in the evidence. As Strauss and Corbin point out, however, each researcher must formulate his or her own “style and technique” (1990, p. 223) of memoing, diagramming, and, ultimately, of analysis.

Some other tips as you analyze:

- Alternative validities always exist. Any discrepancies in the conversations can make for wonderful richness and complexity.
- Noting significant passages of text and identifying the number of the participant during analysis will aid the writing process later on, particularly if the final manuscript requires quotations from the evidence.
- Consider using a computer software program to help organize the data. Each transcript must be cleaned and standardized, and then a program such as NVivo can help you code for themes, search for keywords, diagram, and develop matrices of parallel concepts.
- A return to those original research questions once the analysis is finished will solidify any findings. Have those questions been answered with this evidence? I will often take a legal pad and write each original research question on its own sheet and then read through all my data again, making notes and writing down macro points I see as I go. This kind of brainstorming ultimately informs and supplements my discourse analysis (or selective coding).
- Wolcott (1990) suggests beginning the writing process even before data collection in order to crystallize the research questions, any theoretical framework, and the ultimate goals of the project.
- Consider sending your informants your finished article before publication for verification of contextualization.

Conclusion

I hesitate to bring all of this to any conclusion, given what Wolcott (1990, p. 55) cautioned about: the “grand flourish that might tempt me beyond the boundaries of the material I have been presenting.” Yet I do want to reiterate the importance of the interview as a methodological tool to uncover the meaning in some communicative puzzle. Where surveys can produce a broad and generalized documentation of a population’s habits and attitudes, the in-depth interview – however it is structured – can investigate those superficial statements. The interview can delve into hidden meanings, explore identity and other constructions, and reveal relationships

the person has not only with media but also with others who influence that media usage. However, as this chapter has tried to demonstrate, the interview's power dynamics will shape what is said. Researchers can attune to these power issues by being transparent, self-aware, and sensitive to the biases and inhibitions that might be present.

Historically the interview has been described as both an art and a science such that no one formula will ever suffice, nor will two interviews ever be the same. It is important to note that generalization tends not to be the goal in this technique, but rather the interview offers an exercise in human interaction, a study in relationships and meaning construction, and an examination of the social processes and forces at work in culture, economics, politics, and other aspects of society. This chapter has attempted to iterate the logistics of the science of interviewing while maintaining that the very serendipity, magic, and creativity of "interview as art" might be exactly the reason the in-depth interview should be performed. The ability to so closely investigate someone's motivations or attitudes – particularly in regard to media studies – can reveal so much about the incredible variety of roles that media and other phenomena play in our lives.

NOTES

- 1 This is not a problem specific to interviewing, but one that confronts all methodologies.
- 2 There are many, many ways to conduct grounded theory. I like Strauss and Corbin's 1998 version because it offers such a blueprint for researchers. But some might prefer something without such rigidity.
- 3 For more on memoing and diagramming, I highly recommend the description in Strauss and Corbin, 1998, chap. 14.

Oral History Interviews

Advantages and Challenges of Employing Oral History Interviewing as Part of a Research Project

Mike Conway

ABSTRACT

This chapter focuses on oral history as a method that allows scholars to record and preserve the thoughts and remembrances of people and groups that may previously not have been heard. It is an empowering method, as it demands a personal connection with the subject and the realization that the interview is a collaborative process. The chapter starts with a discussion of the history of oral history as a research method, which started as an added element in historical research and evolved into the central component in memory studies. It also provides practical information for conducting oral history interviews, from working with a university's human subjects committee, finding subjects, recording audio or video, to strategies on how best to tap into those important memories. Finally, it explores analytic strategies for incorporating the interviews into academic research.

Oral history is an empowering research method in media studies. Through oral history, researchers record and preserve the thoughts and remembrances of people and groups who may previously have had little chance to have their voices heard. "Human beings individually as well as collectively make the decisions that change

history,” according to Valerie Yow (2008, p. 186): “We want to know why they made these decisions, how they made them, and even how they got to that point.” Oral history is empowering for researchers because the method demands a personal interaction with the subject, and a realization that the interview is a collaborative process involving both the interviewer and interviewee.

Oral history as a research method has its roots in the field of history as an additional primary source to better understand historical events. But scholars in many other disciplines, as well as the general public, recognized the potential of oral history and have adapted and adopted it for use across a wide variety of projects. While oral history as a historical method is still used primarily to provide a more inclusive and accurate record of the past, in other academic fields the process of remembering, including what people forget or how they reconstruct the past, has become just as important as the historical information itself.

This chapter first examines the history of oral history as a research method in the twentieth century, starting as an added element in historical research to becoming the central component in memory studies. It then takes a look at the latest in memory research, to develop a better understanding of how our brains actually work to code and retrieve events. The following section focuses on preparing for oral history interviews, from working with your university’s human subjects committee, pre-interview research, finding subjects, to deciding between audio and video interviews. The chapter then considers the logistics of the interview itself, including location, length, and tips on how best to tap into those important memories. Finally, it addresses how the interviews are used in academic research, focusing on analytic strategies, transcriptions, legal release forms, and repositories for your original interviews.

Recovering and Interpreting the Past

Chester Burger sat up on his couch on Manhattan’s Upper West Side, looking past the small video camera, and summoned half-century-old memories of the debates on adapting journalism for the new medium of television. “How should you present news with a person? We didn’t know,” remembered the 82-year-old New York native about his work on early Columbia Broadcasting System (CBS) television newscasts. “I remember the one category, if we may call it that, we didn’t try was a female. We never even thought about having a female face or voice in that culture and in that period. It was never even in our minds” (Burger, 2003).

One week later, in Guilford, Connecticut, 86-year-old Robert Bendick talked about those same discussions on television news at CBS. “We were trying to find out what makes a good commentator or news reporter and we tried various people and some were not very . . . didn’t have charisma, didn’t have the delivery that we needed . . . so it was auditioning time on the air, which is about what it amounted to” (Bendick,

2003). That same year, close to 4,000 miles away, 91-year-old Henry Cassirer sat on his patio in Annecy-le-Vieux, France, and explained his role in those mid-1940s CBS meetings. “You see we had the great advantage of not having a public,” remembered Cassirer. “You could try out anything. That gave us great freedom of experimentation” (Cassirer, 2003).

All three memories, separately and collectively, combined with other historical material, provide important insight into the development of one of the most powerful positions in journalism, the television newscaster. The newscasts themselves predate kinescopes and videotape, so they cannot be viewed today. There is little written documentation on the origins of the position later known as news anchor. So, without these recorded memories collected more than 50 years after the event, we would have a limited understanding of what happened. More importantly, less than a decade after these interviews were recorded, all three men had passed away.

These three men all had successful media careers and could not easily be considered marginalized or silenced voices over their lifetimes. But in the particular area of early television news, their important contributions had been ignored until their oral histories were recorded, analyzed, and published (Conway, 2009a). One of the strengths of oral history is its versatility as a research method. You can explore the breadth of a person’s life or you can focus on key events or contributions. Oral history allows you to tailor the process to the research questions at hand.

Oral history can be divided into two categories: oral tradition and personal reminiscences. Oral tradition involves the passing along of information from generation to generation through stories and verse. Prior to the written word, people relied on oral traditions to keep a record of their past. The second category, personal reminiscences, includes the remembering of events in a person’s past, usually prompted by questions from an interviewer. For the purposes of this chapter, we will be focusing primarily on the personal reminiscences area of oral history, which we will call the *oral history interview*.

The Oral History Association (2009) defines the term as referring “both to a method of recording and preserving oral testimony and to the product of that process.” The key elements in oral history include a person interviewing someone about his or her personal experiences, with the interview preserved on audio or video. Oral history is known by several names and is popular in several academic disciplines, as well as with the general public. The process is also called life history, personal narrative, oral biography, memoir, testament, and a self-report.

Oral history is practiced not only in historical and media research, but also in anthropology, literary studies, sociology, linguistics, folklore, psychology, and cultural studies. Because oral history has been embraced across such a wide range of disciplines, both academic and public, specific definitions and details on the purpose and approach can vary. Some scholars use the terms “oral history” and “in-depth interviewing” interchangeably, while others consider oral history a more “holistic” approach (Hesse-Biber & Leavy, 2006, p. 153). In-depth interviewing often includes a group of people who are asked a fairly structured set of questions, while oral

history focuses on the individual, with a more organic approach to finding out about the person's life or a specific period of time.

History of Oral History

Oral history emerged as a valuable research method in the mid-twentieth century as scholars began to push beyond traditional historical research and its emphasis on printed documents as the most important sources. Traditional historical research tended to focus on the people in power, those who left behind a paper trail. Some historians continued to study elites, using oral history to fill in the gaps of information not provided in the printed sources. Other scholars, especially in Europe, began to use oral history to focus on the working class and other groups that might be invisible or marginalized in print sources (Ritchie, 2011).

This approach to historical research became known as social history, a “bottom-up” approach to remembering the past. One of the inspirations in this area came from a Depression era program in the United States. Members of the Federal Writers’ Project, led by folklorist John Lomax, tracked down more than 2,300 former slaves in 17 states and recorded their memories. The project, *Born in Slavery*, became one of the most important resources for understanding everyday life in bondage (Blakey, 2005; Library of Congress, 2001).

Columbia University initiated the first academic oral history project when it opened the Oral History Research Office in 1948. Allan Nevins, a former journalist trained in interviewing people, ran the Columbia effort and took on high-profile projects to interview people for their role in historic events. The social history movement led to the creation of the History Workshop at Ruskin College in Great Britain in 1966. That same year, the Oral History Association (OHA) was formed.

As the technology improved for recording audio, and the interest in social history and critical theory expanded, oral history interviewing moved out of the academy and into the community. State and local historical societies began oral history projects to save the memories of people in their geographic area. Organizations started recording interviews with their long-time members to preserve their stories. Teachers initiated oral history projects for their students. The popular *Foxfire* series of magazines and books stemmed from high school teacher Eliot Wigginton and his Rabun County, Georgia, students conducting oral histories on life in the Southern Appalachian Mountain area (Perks & Thomson, 2009; Ritchie, 2011).

The popularity of oral history also sparked a backlash from traditional historians. If just anybody could do these interviews, what was their value? If hundreds and thousands of these recordings sit in archives across the world with few, if anyone, listening and analyzing them, how does that advance our understanding of the past? The OHA began to craft a set of guidelines and best practices, a process that continues to this day. While oral history's popularity stemmed partly from its low barrier

to entry – access to an audio recorder and the ability to ask people questions – oral history as scholarship demanded a high level of research and understanding of the strengths and weaknesses as a research method.

While historians debated the strengths and weaknesses of oral history, other disciplines began to incorporate the method into their research. Interviewing had long been a part of ethnographic research, so oral history had common ground in that area. Critical theory emerged in literary studies, to study and give voice to under-represented groups. In many sections of society and cultures, women had been denied access to the power structure, so their histories often included few printed documents. Nondominant and marginalized groups may not leave a paper trail, thus oral history became a valuable way to research gender, class, and ethnicity.

Many historians continue to take an epistemological approach, using oral histories to provide a more accurate and textured look at the past. But for other scholars, in an area loosely defined as memory studies, the accuracy of the information is less important than the memory and the process of remembering. For Alessandro Portelli (2009), “[o]ral sources tell us not just what people did, but what they wanted to do, what they believed they were doing, and what they now think they did” (p. 36). Memory studies include research on shared (not individual) memories, which builds on the work of Maurice Halbwachs (1992), who coined the term “collective memory.” For collective and public memory scholar Carolyn Kitch (2012, p. 7), “[t]he concept of memory has become a popular lens through which to see how the past is understood retrospectively and how social groups use ideas about history in order to make sense of their identity in the present. These processes occur over time, a memory is reshaped again and again.”

Memory

Whether you are utilizing oral history to add to the historical record or to understand how people process the past, it is helpful to know how the brain works before embarking on an oral history project. Researchers from several disciplines are studying memory from a variety of approaches, and we can glean important information from these studies to help us better utilize oral history as a research method.

First of all, we have to throw out the old notion that when an event happens, our brain saves the memory and stores it somewhere so we can bring it back later, like a tape recording. Instead, the brain takes different parts of the sensory experience and puts them in different places. So, depending on what question or stimulus brings back the event, the memory can have different details, contingent on how the brain arranges the recovered information (Whittlesea, 2011).

It is a common assumption that the older we get, the less we remember. This is true, but only to a point. Problems with story recall can begin in people as early as their late forties, but in studies, older people only lost about 10–15% more memory

than younger people. In reality, most memory loss happens in the first hour, followed by the next nine hours (Schacter, 2001). If the experience survives the first day, it has a good chance of being saved in the long-term memory. Research shows we have a better memory for either unpleasant or pleasant experiences. Events that are particularly important to us can be recalled in great detail, which Brown and Kulik (2000, p. 51) dubbed “flashbulb memories.” We tend to have stronger memories of events if we have told the story to others over the years or even just gone over it on our mind, processes called *overt* and *covert rehearsal*.

Another interesting aspect of memory is that as time goes on, our memories take on a narrative structure. In studies of both a soldier in a Vietnam War battle and people in New York City on September 11, 2001, the eyewitness interviews conducted right after the events were disjointed, heavily detailed, and very graphic. When those same people were interviewed years later, the memories had been turned into a more coherent narrative with fewer details. We use our memory to make sense of our lives (Allison, 2009; Clark, 2011).

Scholars are concerned with both the *validity* (accuracy about event being remembered) and *reliability* (degree of change in details and structure as memory is retold) of oral history interviews. Unfortunately, in memory retrieval, people can mix in what happened with what they imagined. They can confuse what they saw on television with what they personally witnessed. Even with very detailed and confident “flashbulb memories,” some of the details can be wrong. Researchers say the police practice of showing witnesses mug shots can be problematic. People may take the mug shot image and place it at the crime scene in their mind and be convinced that the person was there (Buckhout, 2000).

In general, people tend to remember accurately the general outline of the experience, but some of the details may be altered. Ulric Neisser (2000) studied John Dean’s testimony during the 1970s Watergate hearings. Dean testified in a manner that put him closer to the events than he really was, when compared to the secret tape recordings. President Richard Nixon’s people thought the discrepancies would damage Dean’s credibility. But his general message remained fairly consistent and the public seemed to ignore the wrong details and accept his overall memory.

More studies have focused on the reliability of memory than the validity. In general, people’s memories tend to be reliable, that is, their versions of long ago events are fairly consistent. But fewer studies have looked at the validity of the memories, that is, how they fit with what we know about the event. Studies also show that people have stronger memories for distinct events or experiences that did not continue through the years. In other words, if someone does the same thing over and over, the first time may stay in the memory because it was new and distinct. But as the same process is repeated over weeks or years, he or she loses the specific details and retains the generalities.

As you might expect, what is happening today, or anytime since the event, colors how people remember the past. A memory is a way of making sense, so people may consciously or unconsciously mold the memory to today’s situation.

Overall, research tells us that we need to approach oral history interview information as we would any evidence – with caution and with other research data to either parallel or contradict the interview details. On the positive side, research shows that if events and situations are committed to long-term memory, there is a strong chance they will not be entirely lost. The person may have trouble accessing a memory, but given the right cues the brain can bring it back. This aspect of memory underlines the importance of the questions you ask and other methods you can use to dredge up long ago memories (Charlton, Myers, & Sharpless, 2006, 2008; Neisser & Hyman, 2000; Perks & Thomson, 2009; Ritchie, 2011; Schacter, 2001; Yow, 2005).

Human Subjects Review

One of the more contentious issues in oral history involves institutional review boards (IRBs) and *human subjects protections*. If you have done any research in a university setting in the United States involving human beings, you already know about IRBs and the paperwork involved. Oral historians have lobbied over the years to have the method excluded from human subjects review, but in most cases in the United States you will have to deal with your university's IRB before you can start your oral history research project.

Institutional review boards have an important role in academic research. They are designed to protect human subjects from harm during research. But the current system has been designed mostly for biomedical studies with little understanding or concern for the differences in other forms of research. Two of the main areas that highlight the differences with oral history are anonymity and record keeping. Regulators want to make sure human subjects stay anonymous and that the data is quickly destroyed after the project is completed. In oral history, the identity of the person being interviewed is often important to the research project and as oral historians we have an obligation to save the interviews and transcripts for future researchers. So the process of getting your project approved may involve helping the IRB staff understand your particular research method and why it may differ from biomedical studies (Schrag, 2010).

Here are a few tips to help you through the IRB process:

- Start early: The process of gaining approval for your project could take weeks, or even months, depending on your IRB.
- Do not conduct any oral history interviews until you have IRB approval. You will not be able to use any data that you collect from human subjects before the approval date of your project by the IRB.
- Find out your university's policy on oral history interviews. A handful of schools have exempted oral history from the IRB process. In most cases you will need to go through an expedited (quicker) or a full (longer) review.

- Keep your project description as broad and inclusive as possible. Once your project is approved, you will have to go through an amendment process if you make any substantive changes to your project.
- Create a list of broad, overall interview questions. IRBs tend to want to see the exact questions you will be asking in the interviews. Gently let the IRB know that these are the type of questions you will be asking in your project but that you have to tailor the specific questions to the person's background and involvement in the project topic.
- Informed consent form: Depending on your IRB's policies, you may be asked to provide the interviewees with an informed consent form. This form spells out the rights and responsibilities of the researcher and the person being interviewed, in most cases giving the person the opportunity to stop participating in the project at any point. The informed consent form is usually separate from the legal release form, which will be discussed later.
- Project length: Pay close attention to the end date on your IRB project approval. After a certain period of time, your project approval will expire, unless you ask for a continuation. If you are given the opportunity, ask for a longer period of time than you think you will need. This will help you avoid extra paperwork if the project takes longer than you expected.

Pre-Interview Research

Frances Buch opened the door to her North Carolina home and welcomed me graciously, if cautiously. Buch had lived alone since the passing of her husband and only knew me from a few telephone conversations. I sensed her tentativeness as I dragged in the video gear and lights. I wondered if my zeal to interview her so quickly after our first phone conversation would hurt her willingness to open up and tell me about her experiences. Frances Buch (Frances Buss before marriage) worked at CBS in New York City from the start of commercial television in 1941 until the mid-1950s. She worked in a variety of areas, both on camera and behind the scenes, and later became the first female director in television. Few people were still alive from the critical early period of television. Frances Buch could provide invaluable insight into an important, overlooked, and understudied era of media history. But she would have to trust me and be willing to recall her experiences.

As I was trying to make her comfortable while I set up the camera, tripod, microphone, and lights, I looked around her living room and something caught my attention. Next to the fireplace, what looked to be a stuffed animal, a lion, peered out from a basket. Without thinking, I blurted out, "Charlemane!!" Frances looked over at me with her eyes widening: "How did you know that!?" In 1954 CBS paired Walter Cronkite with a lion puppet named Charlemane on a morning show in a desperate ploy to match the popularity of chimpanzee J. Fred Muggs on NBC's *Today*

Show. Buch had worked on another short-lived CBS program that involved the lion puppet. She broke into a grin as I told her how I knew the identity of Charlemane. Any tension or apprehension seemed to disappear and Frances Buch and I spent hours discussing her role in early television, providing critical background and details. She had decided to accept me as someone who would understand and appreciate her experiences (Buch, 2008).

You may consider sight recognition of an obscure 1950s television puppet as evidence of mindless trivia – and it might be – but I like to think of it as a benefit of immersing yourself in your area of study. I would not have recognized the puppet without years of studying early television. Frances Buch may have provided a great oral history interview without that moment, but I firmly believe that the more you know about the interviewee’s world, the more he or she will be willing to open up to you with his or her memories. This is an insight I learned as a television news reporter. When I interviewed people without a clear understanding of their expertise, they might give superficial answers. But if they felt that I had an understanding, or at least an appreciation or curiosity about their subject, they would often open up and provide greater insight and texture.

In short, the more you know about your research area, the better the oral history interview. You cannot control the memory of your interviewee, and you may not be able to control the length of the interview or even the location, but you can control the amount of knowledge you bring to the subject. As we learned earlier in the section on brain studies, research shows that important information is often not erased from memory, but you need to provide the right cue to access the knowledge. Just as important, the more you have immersed yourself in your area of the research, the better prepared you will be to react to the answers you receive in the interview.

Interview as Data Collection

I try to approach each oral history interview as if I have only one chance to ask questions and react to the answers. I feel I need to collect all my “data” from this person in one or a few sessions over the course of a day or two. In this scenario, it is critical for me to know as much as possible to ask intelligent follow-up questions on the spot. In reality, I usually have had the luxury of following up my oral history interviews with later phone calls, emails, or other correspondence for clarification. But in some cases, I did only have one chance and those interviews are all I have from that person on my research project.

I learned this lesson during one phase of my television news history project. Because of a lack of funding, I first interviewed some key people by telephone. A month or so later, I was able to secure funding to travel to their homes for in-person interviews. As I transcribed the first phone interviews, I realized they had brought

up names, places, and even concepts that went right over my head. Even though I thought I was well prepared, it became clear I had more work to do. Luckily, I had the time between the phone and in-person oral history interviews to dig deeper into the existing research and to cast a wider net for information. As a result, the second interviews provided better information and insight.

When you are conducting your literature review, do not forget the human element. Since we are concerned with media research, most of what you are hoping to learn may involve the process and work involved in media or how that media was received. But since you are interviewing people, you should also be versed in their living environment. What was life like during the period you are studying for the people you are interviewing? Their work may have been in midtown Manhattan, the streets of Cairo, the upper peninsula of Michigan, or the plains of western Kansas. How did that affect how they did their work? In other words, your mastery of secondary sources should include not just the research topic, but also the geography and living conditions of the location and time period. Oral history interviews can often provide rich detail about those conditions.

Choosing Your Interviews

Oral historians are haunted by the obituary page. Every death represents the loss of a potential narrator and thus an absolute diminution of society's collective historical memory.

Davis, Back, & MacLean, 1977, pp. 4–5

When thinking about whom you should interview for your research project, the easy answer is to focus on the people who were closest to the specific research questions or hypotheses you are investigating. In reality, you often have to make strategic decisions on your oral history interviewing. First of all, how long ago was the time period you are investigating? To put it bluntly, you may want to focus first on the people who may be the oldest or might be losing their memory. As an oral historian, you want to think about their knowledge and experience as important data that you need to retrieve to provide better insight into an earlier time.

The best way to start thinking about potential interviews is to go through previous research and start writing down names. Check personal archives to see if the individual who donated the material is still living. I have had the best success with an approach called snowball sampling. Lindlof and Taylor (2011) consider snowball sampling “well suited to studying social networks, subcultures, or people who have certain attributes in common” (p. 114). I get in touch with one of the first people I find and then ask them to name other people who were involved in that area. They can provide phone numbers or email addresses. Then I contact those people and also ask them for names. If the number of potential interviewees gets large, I start a

database with all the names. Then I can add any information I find out about that person, including who gave me the referral, any mentions in the existing literature, and any contact information.

Through your research, you may have identified a group of people who would be potential oral history interviewees. You can ask yourself several questions about each member of your potential interview group to create a rank-order list. Has the person already written a book or article about his or her experiences? Has someone else written about this person? Has someone else already conducted an oral history interview with this person? Did the person keep a journal during the period in question? If the answer is yes to any of the above questions, you may be able to hold off on talking to this person, for now.

How close was the person to the event or time period you are studying? Would they have been in a position to have first-hand knowledge of what you are studying? I often identify people who may not have first-hand knowledge of the specific topic I am studying at that moment, but they were present, either at the company or at a competing media outlet. They can often provide important context and perspective for the period, but they are not as important as the people directly involved.

Once you start working on your list, contact those you can find. It is best to talk to them on the telephone so you can get a sense of what they may remember and their interest in helping you on the project. Are they retired or are they still working? That can be a critical question because people who are still working often have less time and are less inclined to carve out time for you.

Interview Logistics

Two of the key attributes of oral history interviews are that they must be recorded and they cannot be rushed, whether the conversation be face to face or by telephone. You need to plan for a lengthy discussion on the topic, defined by the Oral History Association (2009) as including “sufficient time allowed for the narrators to give their story the fullness they desire.” The length of an oral history interview can vary considerably and is determined by a number of factors, including the wishes of the interview subject, time constraints, and budget. When I conduct interviews, I hope to record a minimum of two hours of questions and answers.

One of the critical logistical questions involves conducting the interview in person or via the telephone or the Internet. If all of your interview subjects live in your city, the decision may not be that difficult. In most cases though, interviewing by phone or Skype is quicker and less expensive than traveling, and some people may feel more comfortable opening up if there is physical distance from the person asking questions.

You also need to decide if you plan to record the interview on audio alone, or combined with video. Charles Hardy III believes the audio recording is key in oral history because the “articulation of thought and memory are first aural, not visual

processes” (Hardy, 2009, p. 399). For Brien Williams, the visual adds context: “Videotaping reveals physical gestures and facial expressions that can greatly expand on the meaning of the spoken word. A smirk signaling irony accompanying a statement would pass unnoticed in an aural recording, unless noted by an attentive interviewer and indicated in the transcript” (Williams, 2011, p. 268).

Personally, I feel I can make a stronger connection if I am in the same room with the person. My strategy for the important interviews is to first record a phone conversation and then later interview those people on video in person. Through decades of interviewing, first as a television journalist and now as an oral historian, I have come up with some strategies for maximizing the quality of the interviews while working with a tight budget. These tips are for in-person sessions, but can be adopted for distance interviews.

- 1 *Comfortable interview location:* Whenever possible, interview people where they are most comfortable, most likely in their home. They are more likely to open up and talk freely about a topic if they are not nervous or trying to negotiate an unknown space. Quite frankly, when I am traveling, I do not have the money to rent an interview location anyway, so the person’s home is usually the best option I have.
- 2 *Adapt to their schedule:* You want to schedule the interview at a time of day when they are most alert. Whenever possible, let the subject choose the starting time. If they are early risers, be ready to talk to them at 7 a.m. if that is what they prefer. Adjust your needs to their schedules.
- 3 *Limit each session:* Always keep in mind that it is exhausting to sit and try to remember events from long ago. People tend to get tired after an hour or two of oral history interviews. Watch your subject closely to see how he or she is holding up during the interview. Some people try to mask their fatigue and continue. You can often tell when they are starting to get tired. Their once precise and detailed stories start to become more scattered and vague. This could be an example of different recalls of different portions of the subject, but it could be a sign that they just cannot access that information at that point.
- 4 *Pay close attention to interview location and potential distractions:* Once you start the interview, you want to limit the number of interruptions or distractions. If the subject needs to stop the interview for any reason, it may take precious minutes to restart the interview and get refocused on the subject. So I spend a considerable amount of time arranging an interview setting to limit interruptions. I usually ask the person to choose a comfortable chair in the room where they would like to do the interview. If they normally like to prop up their feet, I make sure they have that option. I always ask if they would like a glass of water within reach.

If possible, I ask them to turn off their telephones. During an oral history interview with the late Don Hewitt in his CBS *60 Minutes* office, I quickly realized one of

the most powerful men in television news often answered his own phone, whether the call was from an important politician or just a delivery guy at the front desk dropping off a package. Luckily, Hewitt realized the problem of the distractions and agreed to unplug his phone during the interview.

Recording Technology

Quite simply, without a recording of the conversation, you cannot call it oral history. The recording becomes an aural or visual document. For that reason, you do not want to take any chances with the recording part of the process. Use the best and most reliable audio recorder or video camera that your budget will allow. Bring backup batteries and equipment. Anyone who has spent time recording audio and/or video for a living knows that equipment always fails at the most important time. Have some kind of backup plan in case of equipment problems.

Know your equipment. Even with decades of experience, I always carve out time the night before or on the morning of an interview to go over my video camera to make sure I understand how it works and how to set up and record the interview. Not only will that greatly reduce the chance of a recording problem but it also puts the person at ease. Legendary television news storyteller Larry Hatteberg of KAKE-TV in Wichita, Kansas, says you need to know your equipment well enough that you can set it up easily and without complications when you are sitting in a person's living room. If you draw undue attention to the recording equipment, you can make the interview subject nervous. If you are confident in your equipment, you can carry on a conversation with the person while you get the recorder ready for the interview.

Recording Audio

Most oral history interviews are recorded on audio. Audio interviews are much easier and less obtrusive than video interviews. When deciding on what audio equipment to use, you want to first think about how you would like to use the recordings in the future. If you are merely preserving a record of the interview you may not be as concerned about the quality, but you must be able to easily understand what the person and interviewer are saying on the recording. If you may be using the interviews in an audio documentary or online, you want to make sure the sound is clear and of high quality. If I am going to the trouble and expense of traveling to another location to talk with someone in person, I may as well go the extra step to insure the recording is more than just a historical record and can serve further purposes.

Most audio recorders come with a built-in microphone. Avoid using these microphones because they tend to amplify other sounds and drown out the interview. I have spent countless hours in archives straining to hear recordings using the built-in microphone. Invest in a separate microphone, preferably a lavalier (“lav”) microphone that can be clipped to a shirt, pointing in the direction of the mouth. People usually forget they are wearing a lav microphone soon after the interview begins.

Be sure that you ask your questions in a loud enough voice that you can be heard on the microphone clipped to the subject’s shirt. It is important that the questions are audible in an oral history interview so future scholars will know what questions led to specific answers. Some oral historians use two microphones so both the questions and answers are clear, but that adds another level of complexity and more equipment that can go wrong. I usually stick with one microphone and make sure I ask the questions loud enough that I can later hear them when transcribing the interview.

Listen closely for noise distractions. It is amazing how much noise an air conditioner or refrigerator can make when you are listening to an audio recording of an interview. I have sometimes asked if we could turn off an air conditioner during the interview to limit the noise distractions.

Always wear headphones or at least earbuds when recording an oral history interview. You need to know how the person sounds as the voice is being recorded. If you are not listening to the interview through the recording device, you have no idea whether or not there is a problem with your audio.

Recording Video

If you are shooting the interview on video, you want to be cognizant of the setting within the video frame. You do not want anything in the background to cause a distraction for someone watching the interview later. For these considerations, I use the strategies that I learned as a video journalist. You want a background that is a subtle visual cue of where you are, without taking away from the person or the memories. In other words, you do not want a house plant to appear to be growing out of the person’s head. You do not want a distracting television or computer screen in the background. You do not want to interview the person in front of a window, with the light coming in behind them, which makes it hard to see him or her clearly. If possible, I make sure the chair is a few feet from the wall, so I can focus on the subject and cause the background to be slightly out of focus, once again directing attention to the person being interviewed.

When shooting a video interview, you may also have to make compromises on comfort versus on-camera appearance. I try to avoid overstuffed chairs or couches because a person can sink right down into the furniture. While they may be comfortable, it does not usually present a flattering view of the person. For that reason, I try

to choose a straight back chair, as long as they do not mind sitting in such a position for an extended period of time.

You will also want to decide in advance why you are interviewing the person on video. Are you merely creating a video and audio record of the session? Would you like to use these interviews for an online project or even a documentary? The answers to these questions will determine how you prepare for a video interview. Decisions are usually based primarily on the budget – which for me is usually very small.

With decades of experience as a video journalist, I am comfortable with video cameras and know how to achieve the quality level acceptable for daily journalism. But I also often work alone and want to travel light. I may bring a few stand lights to help improve the look of the interview setting, but I do not have the time or budget for the often hours-long setup time for interviews used for news magazine shows or well-funded documentaries. I always use a sturdy tripod, so my shot is steady and I can concentrate on my questions. I try to find a pleasing head-and-shoulders frame for the interview, and then rarely change the shot during the interview.

When shooting your own video oral history interviews, be sure to sit right next to the camera so you can see the camera screen. I try to position myself so I can keep eye contact with the interview subject and occasionally lean over and look at the camera screen to make sure the person is still in the frame.

Whether you are recording video or audio, be sure to start each recording with key information including your name, location of interview, and date. You can say the names of the interviewees or have them pronounce their names. It does not hurt to also have them spell their names.

Questions

Your questions are the key to a successful oral history interview. The questions are the culmination of all of your research into the subject matter. As you read the literature to prepare for your research project, you should be jotting down ideas and questions. Your questions should revolve around two main areas: (1) What information and insight do you need to help test your hypotheses or to provide illumination into your research questions? (2) In what area of your research does the oral history subject have direct involvement?

For a historian, the traditional printed primary sources will only reveal so much information. The person's experiences will often help you understand the process and context involved in creating those documents or other media. For example, you could combine oral history and content analysis to study the newspaper and television coverage of the riots at the 1968 Democratic Convention in Chicago. In the content analysis portion of the project, you can design a codebook to study the words

and pictures used in the newspaper coverage and the use of visuals and sources in the television coverage. But the content analysis will only allow you to study the message itself. Any inferences about the intent of the journalists involved are speculation. Oral history interviews with the reporters and other journalists may provide insight and context into how and why the riots were covered in a particular way. You can find out what roadblocks the reporters had to overcome and what information or visuals never made it into the newspaper or television coverage.

More specifically, you want to create a list of questions for your oral history interview that is longer than the number of questions you will be able to ask in the time you will have. Spend some time putting the questions in order of importance to your research. Have the questions with you during the session so you do not forget a key area when you get into the interview.

Use your list of questions merely as a guide. Let the people you are interviewing set the course for the interview, within reason. Listen to the answers. Be ready to follow up the answer with a question to provide more clarity and detail. If they want to go into great detail, let them. Some people feel the need to provide as much detail as they can, and if you try to interrupt them you may disrupt their process of remembering the event. Studs Terkel compared oral history interviewing to jazz music: "Have a skeletal framework, but be ready to improvise within that" (Terkel, 2009, p. 127).

Do Not Interrogate

This is not *60 Minutes*. You are not trying to catch the person in a "gotcha" moment. When I show students portions of some of my interviews in which people are providing wrong information, they sometimes ask why I did not grill them on the incorrect information. You want to remember that you are usually dealing with memory issues, not deception. These people may have long ago transposed events and now that is how they believed the event happened. In the case of information that I suspect is incorrect, I will usually ask a follow-up question to see if the person misspoke or if additional information will help them with the memory. If not, I make a mental note to check out the details later. For researchers in memory studies, the transposed events or incorrect details can be a window into how that particular person has made sense of that part of his or her life.

If your topic includes troubling or embarrassing questions for the interviewee, save those for later in the interview when the person is more comfortable with you and the process. I like Charles T. Morrissey's (2006, p. 190) approach of putting the blame on a mythical future researcher. When he has to ask a tough question, he prefaces it by saying "A future historian would rank me as remiss for not now giving you the opportunity to answer this important question." This deflection could save you from an abrupt end to the interview if the person takes offense at the question.

Eye Contact

During the interview, concentrate on the person you are interviewing. Only look at your questions and notes when necessary. If you are recording the interview on video, sit next to the camera so you only have to lean over occasionally to make sure the person is still in the frame. The more you can maintain eye contact and genuinely listen, the better the chance that the person will feel comfortable to open up and talk to you. If you spend too much time fiddling with the recording equipment or looking at your notes, the interviewee will sense your disconnect.

Always end your interviews by asking if the person has anything to add or other topics he or she would like to discuss. Usually, he or she will have nothing to add. But occasionally, that final question can be a prompt to provide details and insight you had not even thought to ask. When the interview is finished, genuinely thank the person for his or her time.

Legal Release Form

Before you leave, and more appropriately before you start the interview, you need to talk to the person about how you are going to use the interview. This is not just ethical, but a legal requirement. Laws and their interpretations are constantly changing, but most oral historians follow the basic rule that, unlike in journalism, the interviewee automatically has ownership and copyright of the interview. People own what they say. So you need to have them sign a legal release form that turns the rights over to you, if you want to be able to use the interview in any scholarly projects. The legal release form should spell out clearly how you plan to use the interview. Are you planning to write a book or monograph? Are you designing a museum display? Do you plan an audio or video documentary? Would you like to post all or parts of the interview online? The more detail you include will save you the hassle of going back to the person, or heirs, for approval for a new usage later. A simple web search of “oral history release form” will provide you with examples. Keep in mind the legal release form is often separate from the informed consent form that you may be required to present by your IRB.

But gaining ownership of the interview also brings responsibilities and potential problems. If the person feels he or she has been defamed by the interview (libel in relation to a transcript, or slander with a recorded version), you may be the person targeted in legal action. The interviewee could also sue for being put in a false light or for having private information revealed to the public. Since defamation only involves living people, sometimes a decision is made to keep parts of the interview closed until a person has passed away. This information is mostly geared to oral historians working in the United States. Laws concerning oral history interviews can

be dramatically different depending on the country in which you work (Neuen-schwander, 2011; Shopes, 2006).

Transcriptions/Electronic Media

One of the key early debates in oral history involved the original recording and the transcriptions of the interview. Some of the early projects, including Columbia University's Oral History Research Office, considered the typed transcript as the primary document. In some cases, the recordings were discarded once the transcriptions were complete. Today, most scholars would agree the recording is the original document and should be preserved. But even with the simplified process of recording and listening to audio and video today, most scholars still find it easier to work with transcripts, especially for research that is designed as a journal article or book.

Interview transcription is one of the most time-consuming but important parts of oral history research. If you have the funds to pay someone else to transcribe your interviews, you will save yourself hours and hours of time. But be ready to still spend some time with the recordings and the transcriptions because someone who does not know the subject is prone to make mistakes on proper names and detailed concepts. On average, transcribing an audio interview takes about one hour per 15 minutes of recorded conversation. This time does allow you to revisit the interview and start to process and analyze the information the person has provided you with.

If I am in a hurry for a conference paper or presentation, I sometimes start with a shortcut method I used as a television journalist. I will listen to the entire interview without stopping, make note of key concepts and ideas and mark where they are on the recording. I put asterisks by comments that I think might work as direct quotes or sound bites. When I am finished, I will go back and type out verbatim the sections I would like to use. I must still force myself to go back later and complete the transcription because it is critical that the information be available for other scholars. Be sure to put all the important information at the top of each transcription: interviewee's name, interviewer's name, date, location, and name of transcriber. You can also add any other information that would help someone who comes across the transcript in the future.

Transcript Approval

During the 2012 US presidential campaign, a journalism ethics debate arose after the *New York Times* published a story revealing the apparently common practice of quote approval for politicians and political operatives in exchange for access. Reporters agreed to send the quotes they planned to use back to the person for approval. Those

quotes were then approved, changed, or deleted without the public knowing about the deal (Peters, 2012). Journalists were quick to criticize this practice. Former CBS anchor Dan Rather (2012) called it a “jaw dropping turn in journalism” which benefited the politicians and hurt the public. Inherent in this debate is journalists’ belief that the recorded answer to a question is closest to the “truth.” If you let people approve quotes, they will attempt to smooth out or eliminate any discrepancies or answers that are not flattering. Also inherent in this debate is that most journalists feel they “own” the interview after it is recorded and the interviewee should have little say as to its use.

This is an area where journalism and oral history diverge. Oral historians must acknowledge the interview is a collaborative experience. Most oral historians believe it is imperative that you send a transcript and a copy of the recorded interview to the person for approval. The interviewee is allowed to delete information, make changes to what was said, or place an embargo on some material until a later date. This version of “quote approval” acknowledges the agency of the people you interview. You are not just collecting data. Interviewees are critical partners in your research.

Oral History Interview Analysis and Interpretation

The strategies and approaches of analyzing and interpreting oral history interviews are as varied as the number of disciplines that have turned to this method to explore their research questions. As with all qualitative research methods, the original research idea and reasons for choosing oral history will help guide you in making sense of what people said and how they said it. In general, we can separate the method into two areas: oral history as one of the sources in a historical research project and oral history or memory studies projects in which the interviews are the primary texts.

In historical research, oral histories are usually utilized as one of several primary sources to try and understand a past event or period of time. The interviews are included along with written documents, personal archives, and other evidence from the past. In these projects, the validity of the information in the interviews is critical. Researchers use the triangulation method, comparing the information in the interviews to other primary sources, to assess the level of confidence they have that the memories are accurate.

Oral history interviews can provide more texture and fill in details that cannot be found in printed historical documents. Oral history provides a human element to historic research. The information can include personal thoughts during an important period, insight into specific work processes, and details on family life. “Generalizations are the curse of oral history memoirs, and specifics are often the nuggets that make them glitter” (Morrissey, 2006, p. 192). Because oral history has

provided access to people and groups previously invisible in historical research, Hesse-Biber and Leavy (2006) consider it a feminist method, by allowing scholars “to get at the valuable knowledge and rich life experience of marginalized persons and groups that would otherwise remain untapped, and specifically, offers a way of accessing subjugated voices” (p. 151).

Oral history interviews also allow you to add personal stories to your manuscript. I try to create a narrative structure in my research, so I often use the oral history interviews as a journalist uses quotations or sound bites in a story. The direct quotes provide a pacing element and add a human element to the media topic. Therefore, when I am analyzing my transcripts, I am looking for sections of answers that would be the right topic and length to fit into the manuscripts in certain points (Conway, 2009b). For those scholars working beyond the printed word, the recorded interviews are a key component to audio and video documentaries.

In the area of oral history projects and in memory studies, the interviews are the data. The validity of the information in the interviews is of less concern than the memories themselves. Scholars accept and embrace the subjectivity involved in the process of remembering past events. For Valerie Yow (2005), oral history’s “subjectivity is at once inescapable and crucial to an understanding of the meaning we give our past and present. To reveal the meanings of lived experience is the great task of qualitative research and specifically oral history interviews” (p. 23). In his oral history work, Studs Terkel valued the unique way each person made sense of past events: “I’m not looking for some abstraction as *the* truth, because it doesn’t exist. What I’m looking for is the truth for *them*” (Terkel & Parker, 2009, p. 125).

The analysis and interpretation of oral history interviews follows a similar path to all qualitative research, a process that is unique to each project but with strategies that have proven successful over time. One of the most popular approaches involves grounded theory. This approach, first introduced by Glaser and Strauss, involves analyzing the interviews and creating as many categories as possible. The categories may be influenced by previous research, but should also percolate from a close read of the interview transcripts (Glaser & Strauss, 1967; Larson, 2006). These categories can be further refined as you read through the transcripts repeatedly. John Bodnar (1989) started an oral history project on automotive plant workers to learn about management–employee relations. Through analysis of the interviews, he realized the individual memories were in part a product of social discourse: “individuals did not remember alone; they discussed the events of their experience and formulated explanations of what had occurred in their lives with other people” (p. 1202).

For those scholars interested in narrative theory, the oral history interviews provide texts that are rich with insight into how people make sense of their lives. Mary Chamberlain (2008, p. 161) considers all oral history interviews as narratives, as

informants move across the terrain of their memories in what may appear a random fashion, highlighting and silencing as they travel through the journey of their lives. If, however, this journey is seen as akin to a plot, then such priorities and silences and the order of telling can convey a meaning that in term requires attention.

In this approach, the method is less of an interview and more of a “jointly created conversational narrative performance” (McMahan, 2008, p. 95).

In some cases, a single oral history interview can inspire a book-length project. Elizabeth Burgos-Debray spent countless hours interviewing a Guatemalan peasant woman, then chose to use only the words of the woman she interviewed, adding an introduction to orient the readers. The book, *I, Rigoberta Menchu*, brought the woman’s story to light with Menchu later winning the Nobel Peace Prize (Menchu & Burgos-Debray, 1984).

Presentation and Classroom Use

An added value of the recorded interview is apparent at conference presentations and in the classroom. While I grumble about the effort that goes into shooting my interviews on digital video, those visual recordings mean that I can show my students and fellow researchers the actual people who were involved in my research. In a 10 minute conference or panel presentation sandwiched between other scholars’ presentations, sound and video clips can draw attention to the work you are doing. In my journalism history class, the students tend to perk up when the boring professor stops talking and they can watch Walter Cronkite remember his early efforts in local television news or Frances Buch explain how it felt to be promoted as a sex symbol as CBS’s first female television director.

Oral History Repository

Another important aspect of oral history is that you are not just interviewing that person for your current project. You are recording the conversation as a record, for use by future scholars. Before embarking on an oral history project, you need to think about how you will save and protect the recordings as well as make them available to others who are interested in the topic. The best solution is to find a library or archive that would be willing to house your recorded interviews. Having an established repository for your oral history interviews not only makes them available to others; if the archive is known for that area of research, it provides one location for future scholars to access material.

Summary and Conclusion

The effectiveness of oral history as a research method has been shown by its acceptance by a wide range of academic disciplines, from narrative studies to psychology.

For media studies, oral history interviews can shed some light on some of the most elusive questions including how and why things happened.

The oral history interview also brings a personal element to media studies. The human aspect and personal connection can enhance both the scholarship and the research experience. Spending time with people who played an important role in media helps bring you, the researcher, much closer to the subject you are studying. The topic becomes more human, more nuanced. If you focus your attention on reception studies, oral history can help you understand how people use media, how it becomes part of their lives.

When you record oral history interviews, you are not only adding to your own scholarship, you are a partner in helping to preserve important information for future scholars, information that may have been lost if you had not gone to the trouble of finding and interviewing your subjects. Oral history can be a rewarding research method, giving you personal access to the very people responsible for the media that are so important to our lives.

Memories of Films and Cinema-Going in Monterrey, Mexico

A Critique and Review of In-Depth Interviews as a Methodological Strategy in Audience Studies

Lorena Frankenberg and José Carlos Lozano

ABSTRACT

Qualitative interviews, a methodology increasingly popular in media and communication studies, are not only useful for studying the meaning construction of different kinds of producers or audiences in the present. They are also useful for exploring past media experiences and for looking at the meaning and importance media had in the past for different types of publics by retrieving memories, feelings, and facts not taken into account in data collected by the media industries. To offer insight into the methodological issues and theoretical considerations media scholars need to address when using this technique, this chapter reports the use of focused interviews in a study on the screen culture of cinema-goers of Monterrey, Mexico, from the 1930s to the 1960s and discusses the methodological challenges of interpreting highly selective, subjective, and distorted-by-time memories of cinema-going in senior informants.

Most frequently during the history of media and communication research, qualitative interviews have been used not as the primary research method, but as one of a number of complementary strategies in participant observation projects, ethnographies, or case studies. Cantor (1971), Elliott (1972), Fishman (1980), Gans (1979), Lester (1975), and Tuchman (1978), who employed the “newsmaking” perspective, for example, included informal interviews with journalists when doing their ethnographic or participant observation studies at different local and national newspapers. Lull (1980), Liebes and Katz (1984), and Morley (1986), on the reception side, also included interviews with members of the families they were observing in their ethnographic projects about the social uses of television. In his seminal study on family television, Morley (1986, 1992) used in-depth interviews to explore questions of differential power, responsibility, and control within the family at different times of the day and night (1992, p. 139).

Since the late 1970s, scholars in the cultural studies tradition have pointed to the need to go beyond the traditional analysis of films as texts (typical of film studies) to include the social and cultural meanings of cinema, focusing on everyday experiences and using a bottom-up approach to film culture. Qualitative interviews are best suited to help scholars look for empirical evidence about these and other topics related to the social experience of audiences with media contents. The theoretical and empirical work of scholars like Allen (1990), Kuhn (2002), Maltby (2006), Meers (2004), Staiger (1992), and Taylor (1989), among others, have established the grounds for the “new cinema history,” an approach that looks at the lived experiences of film audiences and the social experience of cinema-going (Maltby, Biltereyst, & Meers, 2011). Qualitative methodologies based on interviews have proved extremely useful to give a voice to those memories of cinema-goers that were never formally recorded and would likely be lost were it not for these research projects. While the methodology is far from being problem-free – due to the difficulty of bringing to the present facts, behaviors, and feelings from a long time ago – it is the best available tool for engaging with the lived experiences of audience members in their historically situated social and cultural contexts.

Most oral history projects on the social experience of cinema, however, have been conducted in the United States, the United Kingdom, and other European countries, where research on film consumption has consistently been done. In other regions and countries with different historical, cultural, linguistic, and even religious contexts, cinema-going experiences may reveal important differences and patterns. Focusing on such regions might help widen the scope of the new cinema history approach. They remain, however, under-researched.

Employing a film culture audience research case study as a starting point, the central aim of this chapter is to make a case for the usefulness of qualitative interviews as a method for the historical study of cinema-going. Thus, this chapter draws on a study conducted in Monterrey, Mexico,¹ the third largest city in the country, located about 130 miles from the border with Texas. As part of the overall methodological strategy, the study was based on focused interviews about the lived cinema

experiences of 28 local cinema-goers older than 64, centering its attention on their memories of the cinemas and the exhibition of movies from 1930 through 1960, and their consumption of films as children, youngsters, or young adults. In the next section, we discuss some of the key findings dealing with participants' film consumption and their lived experiences of film culture, with the key purpose of illustrating the use and the relevance of qualitative interviews in media and communication research.

Qualitative Interviews and the Exploration of Cinema-Goers' Memories

According to Huggett (2002), informants in projects about cinema-going (or, for that matter, about the reception and consumption of any other medium) based on qualitative interviews do not recall events directly from the past:

Instead, narratives are constructed through a series of negotiations between past and present discourses about a particular topic; between past and present versions of one's self and one's identity; between the agenda of the interviewer and the interviewee; and between the stated topic of the interview and other prescient topics in the mind of the narrator. (p. 15)

For this reason it is always important for us, as qualitative researchers, to distance ourselves from any attempt to consider the discourse of respondents as an objective and definitive account of what they used to do, think, and feel about their media experiences in the past. The outcome of these meaning negotiations may, however, be even more useful than any utopian objective recollection of facts, as they provide a rich and dense insight into the lasting meanings and values attached to participants' media consumption habits and, consequently, about the accumulated long-term importance of that kind of experience in their lives. Qualitative interviews, as well as ethnographic approaches including observations, diaries, and written accounts, are valuable tools to explore these subjective and nonlinear memories and experiences.

As Kuhn (2002) reflects on her own work on British memories of cinema-going, the challenge for researchers using these qualitative methodologies is not doing the actual fieldwork, but the analysis and interpretation of data that are highly selective, subjective, and distorted by time (p. 6). When informants older than 65 are interviewed and asked to talk about their experience of going to the movies when they were kids or adolescents, the fragmentation, distortions, and overstressing are even more selective and subjective. The purpose of historical research on cinema-going, thus, is not to objectively reconstruct the past through the memories of respondents, but to look carefully at the recreation and reconfiguration of that past to grasp

the subjective, personal meanings attached by the informants to their media experiences.

A first step in preparing the fieldwork of any qualitative study is the selection of informants. For that, researchers need to establish a clear rationale for the type of respondents they need to approach and the requirements of age, gender, social class, origin, or any other distinctive category they need to fulfill. The 28 participants in our study were selected and found in homes for elderly people or within the social circle of acquaintances of the interviewers.² The reason for focusing on this age group was to explore the historical attendance of cinema and reception of films as far back in time as possible. By selecting informants older than 65, we were able to explore enduring readings and memories of films and of the social experience of going to the cinema. In the same vein as Kuhn (2011), we were interested in doing historical research into cinema-going, examining how cinema memory works as a kind of cultural experience and as a form of discourse so that we could “explore how the personal or the private on the one hand, and the collective or the public on the other, work together and intersect in people’s memories” (p. 85). As is the case in most qualitative research, statistical representativeness was never the objective of this part of the study. Rather, we sought as much variation as possible in terms of class, sex, and ideological points of view in order to grasp a wide variety of possible routines, ideas, and motives concerning cinema-going in this age group. The level of film consumption also varied widely within our group of respondents, from avid movie-goers in the past to respondents who hardly ever visited a movie theater. Most of the informants were born in Monterrey and grew up in the city, which made their memories of cinema-going specifically about local movie houses and contexts. However, some of them were from other parts of the country, and some of their recollections refer to their cinema-going experiences in other Mexican cities.

In qualitative interviews, the adequate sample size is never known in advance. Rather, according to the “maximum-variety sample” strategy (Patton, 1987, p. 53) qualitative researchers start with a limited number of informants and continue adding cases until their opinions, narratives, and information become repetitive or do not offer any new insight into the topic at hand, what some scholars call “saturation” (see Morse, 1994, pp. 225–229). According to Lindlof and Taylor (2002), qualitative researchers should keep sampling persons, settings, or activities until “a critical threshold of interpretative competence has been reached – when for example, we cease to be surprised by what we observe or we notice that our concepts and propositions are not disconfirmed as we continue to add new data” (p. 129). Patton (1987) explains that using this strategy yields two kinds of findings: “(1) High-quality, detailed descriptions of each case which are useful for documenting uniqueness, and (2) important shared patterns which cut across cases and which derive their significance from having emerged out of heterogeneity” (p. 53). In our project, we decided to start with a relative high number of respondents (28) and, after checking the degree of saturation in their responses, evaluate if we needed to add more cases. Due to the relative homogeneity of the informants (similar age frame and geographi-

cal origin), it was clear when looking at the transcripts of the 28 interviews that saturation had already been attained; consequently, we decided not to augment our sample size.

The 28 individual interviews were conducted in 2010 and 2011. Most of the informants were contacted and interviewed in elderly homes in Monterrey. They were approached by graduate students who first got permission from the administrative office of the retirement homes to talk to the residents. Interviewers selected only respondents who were native to Monterrey or who had lived in the city since they were kids, in order to concentrate the findings on Monterrey cinemas and their social and cultural context. A few of the respondents were relatives of the graduate students doing the fieldwork or of their peers. In order to provide a more relaxed environment for respondents, interviews were performed in their place of residence. The interviews were semi-structured, whereby the interviewers used a thematic questionnaire to keep the interviews focused, leaving a large degree of space for the respondents' own stories and spontaneous memories.

The terms used to describe this kind of qualitative interviews vary among scholars. Lindlof and Taylor (2002) call them "respondent interviews," pointing out that despite it being possible to vary some questions from one person to the next, the questions should follow a standard order so that responses can be directly compared across the entire sample (p. 178). Using the same term, Jensen (2002) explains that in "respondent interviews" the interviewee is conceived as a representative of one or more social and cultural categories: "The assumption is that these categories are inscribed in, and can be recovered from, the respondent's discourses with reference to the media" (p. 240). Patton (1987) on the other hand, calls this type of interview the "standardized open-ended interview," noting that it consists of "a set of questions carefully worded and arranged for the purpose of taking each respondent through the same sequence and asking each respondent the same questions with essentially the same words" (p. 112). In our project, while we followed the procedures outlined by Lindlof and Taylor, Jensen, and Patton, we prefer to identify this kind of qualitative interview using the more general term "focused interview" (the term first used by Merton and Kendall in 1946 for a qualitative interview centering on the subjective experiences of persons involved in particular media experiences, like watching films in a particular setting), to distinguish them from in-depth interviews that are much longer and that cover many topics instead of concentrating on just a few.

This focus was crucial since many respondents were highly motivated to talk about cinema, had very vivid memories, and often referred to specific moments they remembered. An attempt was made by the interviewers to cover first the childhood memories, then the youth memories, and finally the adulthood memories, repeating in some instances the same questions. Interviewers would explain to the informants at the beginning the need to first provide recollections of one period of time and then the following one, and then, in several instances, they would phrase the questions using references to the period they were inquiring about (i.e., "Please tell me

the names of the cinema houses you used to go to most frequently when you were a child/young/an adult"). Of course, despite this strategy, informants still decided to move freely from one epoch in their lives to others, but at least the provision allowed for some focus on each period. The length of the interviews differed depending on the storytelling capacities of the respondents, with an average length of around one hour per interview.

The interviews were transcribed by the interviewers verbatim and analyzed using the software HyperRESEARCH. Like any other software for qualitative analysis, HyperRESEARCH makes the coding and retrieving of comments and responses faster and easier than with manual strategies like working with the transcripts directly in Word files. For the analysis, we used the "thematic coding" approach (Jensen, 2002), "an inductive categorization of interview . . . extracts with reference to various concepts, headings, or themes" widely used in media research (p. 247). We started with the identification in the transcripts of each interview of the themes or frames prefigured in the open-ended general questions included in our base questionnaire, but we also generated a great number of new categories by carefully looking at the collected data to find topics, reactions, and issues not considered beforehand in our research design. The final list of themes included choice of movie theater; frequency of attendance; information about specific films; cinema-going motives; origin of preferred films; opinion about Mexican, American, and European films; and so on. Due to the relative homogeneity of the group in age, and consistent similarities between them in their memories and discourse about their cinema-going, we are confident that the number of interviews was adequate to explore the lived experience of films and cinema by this age group of Monterrey, Mexico, residents.

Taking into account that the heyday of movie-going within people's life cycle is before the age of 25, the largest part of the stories of our respondents focused on the period between 1935 and 1965. Although this is a very broad time span, spanning the heyday of movie-going as well as the decline of audience attendance, many respondents talked about it as if it were one homogeneous period. While respondents considered these evolutions to be developments within the same film culture, they strongly distinguished it from the next phase in cinema history. In the respondents' minds, the introduction of the multiscreen or multiplex cinema resulted in a totally new film culture.

The Setting

Before discussing the usefulness of focused interviews as a method to retrieve memories of cinema-going in our informants, it is necessary, as in any other qualitative empirical study, to establish the setting and historical context of the research topic – in this particular case, the availability of cinema houses and the type and number of films they were exhibiting between the 1930s and 1960s in Monterrey, Mexico.

With a population of 134,000 inhabitants, Monterrey had in 1932 eight formal movie theaters. By 1942 the number had increased to 25, spreading the options of screens to other parts of the city. Ten years later, the number went down to 20 and by 1962, with the end of the golden age of Mexican cinema and the popularization of other means of entertainment for the middle classes (Rosas Mantecón, 2000), it had dropped to 14. In addition to the movie palaces and regular cinemas in the center of the city, there were a minimum of 46 cinemas called “terraces” (*terrazas*), modest establishments with wood benches instead of individual seats and without a roof, located mostly in working-class neighborhoods and exhibiting second-or third-run movies after dark with very cheap entrance costs.

From the 1920s to the 1930s, Hollywood movies almost completely dominated Monterrey screenings. By the end of that decade, however, the reduction in the number of Hollywood films during World War II, as well as local government policies supporting the production and distribution of Mexican movies, led to the development of the golden age of Mexican cinema. Monterrey screens started to showcase national films widely and consistently, and for the first time local audiences had a choice between Hollywood and Mexican productions.

In 1936 the release of three films heralded the formal beginning of the golden age of Mexican cinema and in particular of its most successful genre, the *comedia ranchera* (rural comedies full of folklore, songs, horses, traditional dances, and so on, which frequently presented stories about love between characters from different social classes): *Allá en el Rancho Grande* (Out on the Big Ranch), *Cielito Lindo* (Beautiful Darling), and *Ora Ponciano* (Hey, Ponciano). The first of the three films, in particular, was massively successful, not only in Mexico but also all over Latin America, significantly enlarging that market for Mexican films. In 1937, 38 feature films were produced, 22 of them in the *comedia ranchera* genre. By 1938 the Mexican film industry was firmly established as such, producing 58 movies and exporting many of them to the rest of Latin America (Vidal, 2011, p. 51).

Memories of Cinema-Going: The Relevance of Focused Interviews in the Exploration of Film Audiences’ Experiences

Discussing the findings of qualitative interviews is not as straightforward as discussing quantitative data. Instead of statistical tables, qualitative researchers ground their analyses in field notes, transcriptions, interview quotes, and descriptions. The data gathered, however, are usually too extensive and voluminous and a great deal of material needs to be left out. For that reason, focus is essential. Analysts should strive for the right combination of description and in-depth quotations needed to allow readers to fully understand the situation and the thoughts of the people represented

in the report. It is important to stress the need to achieve the right balance between description and analysis. As Patton (1987, p. 163) explains:

endless description becomes its own muddle. The purpose of analysis is to organize the description in a way that makes it manageable . . . An interesting and readable report provides sufficient description to allow the reader to understand the analysis and sufficient analysis to allow the reader to understand the interpretations and explanations presented.

In the next section, we try to tackle precisely that point through the description and interpretation of the findings of the screen culture project in Monterrey.

Selection of Movie Houses and Films by Audiences, 1930s–1960s

For the 28 men and women older than 65 in our sample, going to the cinema was one of the few alternatives for leisure in the city. When asked about other recreational activities available, most informants mentioned only sport activities like baseball (a very popular sport in Monterrey at the time) or soccer, or, when they were kids, playing on the street. Some also talked about going to the circus when one came to town or about going to nearby farms or ranches on picnics. The rich, they explained, could go to the Casino Monterrey (a very exclusive social club with restaurant, cafeteria, game rooms, and ballroom), but they had no means for another kind of recreation than going to the movies.

Most respondents explained that they did not select particular films, but rather particular movie houses. Some would go to the big palace closest to home, avoiding some other cinema houses because of their lower status. Others, from low-income households when they were kids, asserted that they would go to the nearest neighborhood cinema, a *terrazza*, to see second- or third-run movies.

It was clear from the interviews in Monterrey that cinema houses were clearly connected to our respondents' "mental maps" of the city. In fact, a large number of them mentioned their home address at the time and then the location of the movie house they attended, making reference to other relevant sites like markets, buildings, or streets nearby. For lower-income respondents, the big movie palaces were inaccessible and they would go to their nearest terrace, making clear that these neighborhood cinemas were attended only by people living close to them. Some of them related in a proud tone that later, as youngsters or adults, when they had a job and some money available, they had gone once or twice to the downtown movie palaces to watch a movie (frequently a Mexican big event film), emphasizing the distance they had to travel to get there.

Our informants' memories about cinemas in Monterrey during this period establish very clearly the importance of the cinemas in their daily lives. Asked about their

favorite movie theater in their childhood and youth, most of them clearly remembered the name of the cinema they had attended the most. The reason for going to that particular venue and not another one was typically its closeness to their homes. They explained that, it being peaceful times where you could walk freely on the streets (even as children), they would always walk to the movies. The most frequently mentioned cinemas were located either in the historical downtown of the city or on Madero Avenue, a modern and fashionable area during the 1940s demarcating the limits of the downtown area with the north of the city, where most factories were established. Nancy,³ a 70-year-old woman, put it in these terms when asked about her preferred cinema when she was a child:

NANCY (b. 1941): Well, it was not a question of preference; it was a question of what movie theater was closer to our home . . . [Because of that] the Rodriguez cinema was the one our parents always chose for us.

However, some of the respondents also preferred certain cinemas because of their formal features. Some made reference to the big palaces and the nice decorations and architecture.

ELOISA (b. 1929): The decoration was beautiful . . . one of them, the Elizondo, had an oriental decoration, with pagodas and statues. And in the Florida, if you looked at the ceiling when the lights went off, you would see stars scintillating.

BIANCA (b. 1942): I remember the curtains. In the Palacio cinema, one of the most – let me put it this way – posh and chic, the curtains would open and I would think: “How is it possible [to have] such a tall, well structured beautiful and elegant curtain.” I remember clearly the seats, very comfortable and well fixed to the floor, and the carpet in the aisles.

For our respondents, thus, cinema houses were more important than the actual films being exhibited when they decided to go to the movies. In contrast to the assumptions of traditional film scholars about film texts being the most – and sometimes only – relevant factor accounting for the interest and attraction of viewers, our fieldwork, based on focused interviews, allowed us to confirm what other studies in new cinema history have found: going to the movies was more about companionship, social interaction, and the integration of movies into the routines of daily or weekly life in our Monterrey informants than about the contents and meanings of specific films.

Social Class Differences

Avoiding the temptation of some other qualitative studies on cinema-going which focus only on nostalgia and ignore the important role played by, among other variables, social class, our project selected respondents from different socioeconomic

status and included questions related to differences in the economic background of people attending different cinemas in the city. Thanks to this strategy, similar to the one used by Meers, Biltereyst, and Van de Vijver (2010, p. 274) in Belgium, we were able to identify the mental maps of cinemas and cinema-going experiences according to the economic position of the interviewees.

Some respondents, for example, acknowledged avoiding some cinemas, despite their proximity to their homes, because they were for people of lower socioeconomic status. In a city with a heavy presence of workers and migrants due to the numerous factories and the industrial boom, and a growing middle class of white-collar workers and managers, class differences were reflected in the selection of movie theaters. Olga (b. 1923), despite trying to use neutral wording, ended up describing people who attended the Obrero cinema as *burdos* (rough, vulgar) and as people unable to speak properly. Others, like María Elena (b. 1934), were careful not to use adjectives:

MARÍA (b. 1934): I stopped going to the movies more or less when the Elizondo cinema was destroyed [in 1982] . . . There was also the Lírico, but the Lírico was for . . . for . . . extremely . . . for the lower classes . . .

And what kind of people used to go to the Florida and the Elizondo?

MARÍA: Sort of like us, the middle class.

Were the people attending the Elizondo cinema different from the people attending the Maravillas?

ARTURO (b. 1927): They were different type of people. [The people attending the Elizondo cinema] would go very well dressed and immediately you would realize they were people with money . . . they paid more for the quality of the movies and for the features of the building . . . they liked movies where good manners were shown. It was very upscale . . . with very nice movies. The Encanto cinema always had a full house. You could smell the perfumes [of ladies] all over. People were very well dressed, like in the Elizondo . . . in the Maravillas [in contrast] people would go dressed anyway they liked.

Ernesto (b. 1922) explained that he would usually go to the upscale cinemas in the downtown area, always avoiding the neighborhood cinemas, like the ones in the Independencia, a sector of the city “with bad reputation.” Asked if there were some differences between the cinemas downtown and the neighborhood cinemas or terraces, another informant answered:

ARTEMIO (b. 1944): Of course! There was a saying, that in the Alameda cinema the employees would give you a big stick [when entering the cinema] to kill the rats. People had bad manners, they spat on the seats and all the seats were in bad shape. You could notice the lack of education because of the aggressive behavior. That’s why we would avoid going to those cinemas.

As discussed above, one of the advantages of using focused interviews is the possibility of addressing cultural and social contexts from the perspective of the respondents. One of the informants, from a working-class background, mentioned that he would go to the Eden, located in the lower-class neighborhood Independencia, across the Santa Catarina river, because he lived there for a while, when his family arrived to Monterrey when he was a kid. "That's the time when I learned how to behave in a belligerent and problematic manner," he said jokingly, adding that the youth gangs would throw stones to any outsider walking on the streets of the neighborhood.

Francisco (b. 1927), whose father worked for 40 years at the soap factory La Reynera, explained that when he was a child he had to work shining shoes on the street. He would give his father all his earnings because of the low wages the latter received at the factory. Every week, his father would take only three or four of the nine children to the neighborhood terrace located close to their home, and the following week he would take the others, because he could not afford to take all of them at the same time.

FRANCISCO: We would go to the movies always at night, after 8 p.m. when it was getting dark. As soon as it was dark, the show started, because the screening was in a backyard, not in a closed building. Terraces were like that. Once in a while he would take us to a movie theater, but only in very few occasions . . . In the terrace there was no ceiling. When it started to rain, we had to run and leave the movie.

Egidio (b. 1915), at 96 one of the oldest informants in the Monterrey sample, explained that when he was just a kid, an illiterate blacksmith neighbor would pay for the movie tickets for him and other boys as long as they read the titles of silent movies to him.

These findings show that even in the recollection of past film consumption experiences, social class is one of the most important variables able to account for significant differences in the consumption and appropriation of films among audience members. The cultural capital available to each class and their social and economic context are clearly influential in their selections, choices, and attitudes. Consequently, it is crucial to include persons from different social classes when selecting informants in projects attempting to understand the complex relationship of audiences with any kind of media.

Memories of National and Foreign Films

With qualitative interviews, it is possible to trigger memories otherwise forgotten. As mentioned by Deacon, Pickering, Golding, and Murdock (1999, p. 301),

the fallibility of human memory may lead to omissions, compressions, elisions and idealizations in the experiential record provided by the interviews . . . [but] it is

beneficial to regard oral forms of evidence as an important mode of bearing witness to the past, of providing testimony to events and experiences that have been historically lived through.

In our study, respondents mentioned the titles of around 15 national and 43 US movies. Coincident also with the boom of Mexican cinema, most of the national films remembered were from the 1940s, the decade when World War II and its difficult aftermath diminished the flow of Hollywood films to the country, and where the financial and distribution incentives for Mexican productions were at their highest (Fein, 1996; Serna, 2006). From the 1950s on, however, most titles remembered by informants were of Hollywood films (14), while Mexican pictures were hardly remembered (only 1 of the 15 Mexican movies they made reference to was produced in this decade).

The respondents had an ambivalent attitude toward Hollywood productions and national films. On the one hand, they had excellent comments about most Mexican movies and actors of their childhood and youth but on the other they also praised Hollywood movies and remembered US celebrities in affective ways.

Mexican Films

Middle- and lower-class informants were clearly partial to Mexican movies when they were kids or adolescents. They mentioned mostly Mexican actors and titles as their favorites. Many female informants said they really loved the Mexican melodramas of the epoch. Ernesto, himself not fond of that Mexican genre, remembered the time when his mother and her sister begged him to take them to the cinema to see *Cuando los Hijos Se Van* (When the Children Leave Home) a movie that premiered in 1941. He took them to one of the “big cinemas” on Madero Avenue and sat between the sisters. He recalled that both sniffed during the whole picture, making him anxious and uneasy. After the movie, he took them home, none of them saying a word during the drive. As soon as they arrived, his mother quickly got out of the car and went directly into her bedroom. After parking the car, Ernesto went to see her and found her crying. She told him: “Here I can cry all I want and nobody will be annoyed, nobody will tell me to shut up.” He concluded: “Mexican movies were such a drag.”

Another female informant, Nancy, also talked about a Mexican melodrama of the epoch leaving a lasting impression on her: *Nosotros los Pobres* (We, the Poor), a movie starring the male idol Pedro Infante which premiered in 1948. Showing the same emotional connection with urban situations and familial problems as the other female respondents, Nancy remembered uneasily that in the movie a small kid dies and another loses his eye violently: “Till today, I am unable to watch that movie again.”

Hollywood Movies

Some informants said they did not like US movies because they didn't understand English and were not able to follow the subtitles (in Mexico dubbing foreign movies was never mandatory nor common). It was more difficult for children to follow the subtitles, so some of the informants reported not watching US movies during their earlier years:

NANCY: there were American movies but we would not go and see them. We would not go because we didn't understand them, we weren't able to read the subtitles . . . As an adolescent I definitely started to watch US pictures, on color and such, but not as a kid.

Others claimed that cheap movie houses and terraces exhibited Mexican films only, explaining that they were not able to go to the cinema palaces where Hollywood films were shown because of the ticket cost.

JUAN (b. 1943): Terraces were more geared towards families; they showed mostly Mexican films . . . they exhibited old movies only, never new releases. If you wanted to see premieres you had to go to the cinema houses in downtown.

Not all working-class informants, however, liked Mexican movies better than American ones, especially the older ones who started going to the cinema as kids before the beginning of the golden age. Herminio (b. 1924), from a rural background, said that he loved to go see US films (apparently Westerns), the reason being that the characters "would get up in their horses and go and shoot their pistols." Middle- and upper-class informants, although sympathetic to Mexican movies from the 1940s, reported viewing and enjoying Hollywood movies, and admiring stars like Clark Gable, Rock Hudson, Ingrid Bergman, Bette Davis, Doris Day, Greta Garbo, Audrey Hepburn, James Dean, and others. As in the case of informants in other countries (Biltereyst et al., 2011), Monterrey respondents rarely remembered any movies in particular, but were very lucid about their favorite Hollywood stars.

In another example of how widespread and popular Hollywood movies were around the world despite cultural and geographical differences of the audiences receiving them, Monterrey respondents, in a similar fashion as respondents in countries like Belgium and the United Kingdom (Biltereyst et al., 2011; Jancovich, Faire, & Stubbings, 2003), repeatedly mentioned big event movies like *Gone With the Wind*, *Ben-Hur*, and *King Kong*.

NANCY: *King Kong*. For me, *King Kong* gave me the most horrendous shock in my life [laughs]. In its first version, of course. At the end of the movie I went home

extremely scared, I had nightmares with it I don't know how many nights afterwards. For me, it was something as . . . Oh my God! And later there were new versions done and they still made an impression on me, but when you are older you realize the fiction, the tricks . . . but the first time . . . What a horrible thing, Oh my God! For me, *King Kong* gave me the biggest trauma of my childhood!

For some informants, *Ben-Hur* was one of their favorite movies of all times. Lucía (b. 1944), for example, explained that she loved the movie since the first time she saw it, adding that she still does not get tired of watching it every year, when it is shown on Mexican television during Holy Week.

European Movies

Very few informants mentioned European movies. The film market in Mexico had been dominated by Hollywood and by local productions since 1917, and European films were not that common, although during 1962 they made up 13% of total screenings. The more liberal character of European films, however, clashed with the rigid morality of the epoch, and the presence of nudity and strong topics in the pictures reduced their programing only to poor cinema houses and led to their being perceived as pornography. Some of the informants, especially women, made reference to this perception when asked about the movies they liked to watch when they were in their adulthood:

- TERESA (b. 1935): Only American ones! Mexican movies started to become sort of ugly and we stopped watching them, and about European pictures, we would watch them depending where they were playing. If they were programed in cinemas showing only pornography, we could not go there!
- NANCY: Definitely, only American. European ones . . . I don't know why they are so crude, so very . . . open-minded . . . too . . . I don't like that . . . nudity and such go against my principles.
- ARTURO: Once I went to the Alameda cinema because I was told it was showing an "art movie," one of those Italian pictures very highbrow for the general public . . . I watch them now and I am able to catch their meaning, but then you would only go to watch the naked girls.

Without specialized cinemas on art or *auteur* films, and very scarce highbrow cultural tradition and infrastructure in the city, most informants were unable to mention alternative noncommercial films, directors, or actors. Only two of the respondents, the oldest in the sample, mentioned some of the classic European movies of the 1930s and 1940s: *The Blue Angel* and *Bicycle Thieves*.

ERNESTO : There were some Italian movies at that time that were very good. There was one about a man whose bicycle is stolen: *The Bicycle Thief* [sic] was called. Italian films like that one were a guarantee. They were interesting and very well done.

The memories and preferences of movies by Monterrey respondents, thus, seemed to be related to both the limited supply of films by local cinema houses and what they felt were closer to their own culture and context. On one hand, Hollywood control of the distribution and exhibition of motion pictures in Mexico for the most part of the 1920s to the 1960s allowed Hollywood genres and stars to become popular among the viewers. On the other hand, as soon as there were enough national films available with good-quality production values addressing more culture-specific topics, Monterrey audiences showed a strong preference for them, and their cherished memories of Mexican stars and plots from that period reflect the high relevance they exerted on them.

Cinema-Going, Family, and Social Interaction

Despite the significant historical, cultural, and geographical differences between Monterrey and cities in the United States or Europe during the same period, the findings of our interviews show striking similarities in the way cinema-going was experienced by Monterrey audiences and is still remembered. The elder inhabitants of Monterrey seem to relate a good deal to the kind of treasured memories, choice of movies, film consumption rituals, reasons for cinema-going, and personal preferences that are characteristic of respondents in studies done in Europe and the United States.

As in the case of Flemish (Biltereyst et al., 2011) and British (Kuhn, 2002, 2011) cinema-goers, Monterrey informants' memories about going to the movies were much more about social and ritual aspects than about particular films. Most of the times, they did not recall specific movie titles and frequently they were unable to remember the name of the actors. However, they were clear and reiterative about what going to the movies represented for them when they were kids or young. Some talked about how they loved to go to a particular big palace because of its decoration and the little lights on the ceiling creating the impression that they were contemplating stars. Others mentioned that they would go to a particular theater because there were contests and prizes during the intermission. A male informant, in this respect, explained that on Wednesdays, in some movie houses, there were song contests at the intermission, or requests for the whole audience to sing particular songs, following lyrics projected on the screen.

Others talked about going to the cinema on particular days of the week with their parents or their friends regardless of the movies being shown. Antonia, an 80-year-old

woman, when asked “What comes to mind when you think about going to the movies as a kid?” answered: “Going out the four of us” (with her parents and sister). Beatriz, 72, answered to the same question: “My best friends, my friend Yolanda . . .”

When questioned about who would select the movie they watched when they went to the cinema with somebody else, the recurrent answer was that they would see what their preferred movie house was showing at the moment, regardless of the genre or topic.

ERNESTO : Usually I would go to the cinema with my brother, but we wouldn’t choose the movie we would see. They [the movies being played in the movie house] were the same as the ones being shown in other theaters in the city. For us it was not a matter of selecting titles, we would just go. We would go to the cinema and we would watch any movie that was playing.

Some cinema-goers, especially women, were more selective and would go to see mostly romantic comedies, but very few acknowledged deciding to go to the movies only when they wanted to see a particular film for its topic, actor, or director (except for blockbusters like *Ben-Hur*).

Memories of Plots and Movies

Memories about the whole plot of a movie were scarce. However, focused interviews allowed informants to intertwine different levels of experiences in their narratives. In this case, they were likely to remember specific movie scenes that had been particularly relevant or shocking to them. An 88-year-old woman, for example, when talking about one of her favorite films, was only able to recollect a scene of “a movie of Betty Davis” where, having nothing to wear for a big party, she takes a curtain and makes a dress out of it (she may have been referring to *Gone With the Wind* and Vivien Leigh, confounding both the film and the actress). A 96-year-old male informant recalled a scene of a movie he saw when he was a kid, where the protagonist becomes blind after gunpowder from his shooting rifle got into his eyes, but he was unable to remember anything else about the film. Later, he recalled that when he was married he went to the movies several times with his wife, but he was unable to remember the title of a single movie they had watched. The scarcity of memories about complete stories or plots of particular films, in contrast with lucid and detailed recollections of how, when, why, and with whom they used to go to the cinema when they were kids or young, suggest that specific movies were for the respondents never the main reason for going to the movies.

In sum, for our sample of old Monterrey movie-viewers, cinema-going was a vivid and extremely relevant part of their lives, especially in their childhood and youth.

Going to the movies was an excuse to interact with relatives or friends, to escape hot weather, to be entertained in a city with very limited leisure options. Memories of movies, as in Great Britain, Flanders, and other regions where cinema-going has been studied, are more about specific, dramatic, or shocking scenes or about favorite stars than about plots or contents or directors. Except for the big event movies clearly remembered and liked, the rest of the films watched during their childhood or youth were just a succession of nondistinctive events providing entertainment, escape, and excuses for wider social and cultural activities.

Discussion

As can be corroborated by looking at the findings, qualitative interviews are not only useful for studying the consumption and appropriation of media contents by audiences in the present. They are also useful for exploring past media experiences and for looking at the meaning and importance that media had in the past for different types of publics by retrieving memories, feelings, and facts not taken into account in data collected by the media industries. It is important to reiterate, however, that the discourse gathered through interviews in these types of studies is not equivalent to an objective recollection and description of behaviors and attitudes by the respondents, but a negotiated, subjective, and somewhat distorted account of how they look retrospectively to the past from the present. As Huggett (2002) explains, oral narratives tend not to organize themselves in sequential and chronological terms but around pivotal events in the respondents' life experience or perspective: "In the service of such narrative agendas, separate dates and times are conflated and disparate events are linked in order to make a particular point in a meaningful way" (Huggett, 2002, p. 20). Instead of affecting and diminishing the usefulness of the findings, these processes, common when interviewing people about their media habits and consumption, allow the researcher to go beyond the simple enumeration of facts and to gain some insight on the subjective and complex meanings audience members attached to them.

A particular strength of having open-ended and flexible question guides instead of fixed items in a formal questionnaire is that the researcher allows the interviewee some room to deviate from the agenda imposed by the former and to focus on his or her own salient memories, themes, or perspectives. Monterrey's respondents went beyond the topics we asked them to cover and included references about the city as a whole, the social atmosphere at the time, the absence of crime and violence in the city in that period, their relationships with friends, partners, and relatives. The role of the interviewer, however, is never neutral, and his or her presence, style of asking questions, and of establishing rapport, exert some influence on the way informants react and remember things. Our informants had to answer questions about their cinema-going habits, their memories of particular films and cinemas; when doing so,

they had to make an effort to isolate parts of their holistic experience where going to the movies was only a part of a much wider context of leisure activities, social interaction, and cultural experiences.

For decades, film studies and film history have concentrated on detailed and sophisticated analyses of the content, structure, and formal features of films, or on the biographical, ideological, or aesthetic characteristics of directors, assuming that all the necessary clues for the prediction and understanding of viewers' decodings lie within the movie text: "film history had been written as if films had no audiences or were seen by everyone and in the same way" (Allen, 1990, p. 348). Qualitative research on actual audience members, like the one presented here, shows the limitations of those assumptions. At the same time, it reveals the rich contextual historical, social, and cultural factors that produce multiple and contrasting readings and appropriations of the films' meanings, as well as the relevance for audience members of many aspects that are completely unrelated to the meanings embedded in particular movies but have to do with the social rituals of going out with friends or relatives, enjoying cinema palaces for their decoration, and experiencing emotional connections with particular actors or actresses regardless of their specific roles in particular films.

NOTES

- 1 This project is a replica of the Belgian (Flemish) project "The Enlightened City" (Biltereyst, Meers, & Van de Vijver, 2011) conducted in Antwerp and Ghent.
- 2 Interviewers were master's and doctoral students Marcela Garza, Oscar Miranda, Beatriz Inzunza, Brenda Munoz, Miguel Sanchez, Elsa Flores, and Frida Godínez (Monterrey Institute of Technology), Karla Carrillo (Metropolitan University of Monterrey), and Gabriela Nallely Hernández Villanueva (Autonomous University of Nuevo León).
- 3 In order to protect the privacy of the informants and to comply with the confidentiality agreement signed with them, the names used in this chapter are pseudonyms.

Conducting Media Ethnographies in Africa

Tanja Bosch

ABSTRACT

This chapter explores the methodology of ethnography in postcolonial Africa, with specific reference to anthropological media research. The chapter draws on an ethnography of a local radio station in South Africa as a starting point from which to make several observations about media ethnographies and anthropological approaches to media production and consumption. It outlines how the chosen methodology revealed unique characteristics of the local, as well as how the findings and experiences could be related to national and regional contexts. Moreover, the chapter explores notions of reflexive “back-yard” or “native” ethnographies, and reveals the complex relational issues that can arise from this approach. This case study is premised on the notion of media as a collective mediation of culture; and argues that the practice of ethnography allows for a refreshing departure from the more common arm-chair textual analyses that permeate media studies.

It's another typical day at Radio X, a local radio station in the shadow of Table Mountain, inaugurated as one of the seven wonders of the world in 2012. DJs are bustling about getting ready to go on air; producers are chatting animatedly on their phones, setting up interviews; others are downstairs broadcasting “pavement radio” to local factory workers; and a group of teenagers are upstairs in the meeting room

discussing hip hop and social change. And perhaps I'm the only one out of place because I'm writing field notes on my laptop, but nobody seems to notice.

This chapter explores the research methodology of ethnography in postcolonial Africa, with specific reference to anthropological media research. It draws on an ethnographic study of a local radio station in South Africa as a starting point from which to make several observations about media ethnographies and anthropological approaches to media production and consumption. The chapter outlines how the chosen methodology revealed unique characteristics of the local, as well as how the findings and experiences could be related to national and regional contexts. Moreover, it explores notions of reflexive "backyard" or "native" ethnographies, and reveals the complex relational issues that can arise from this approach. This case study is premised on the notion of media as a collective mediation of "culture," and argues that the practice of ethnography allows for a refreshing departure from the more common armchair textual analyses that permeate media studies. First, I provide a brief summary of the main tenets of the ethnographic methodological approach, and discuss how media scholars have adopted these practices. I then outline the specific case of an ethnographic study of a local community radio station in South Africa, and reflect on the resultant issues of authority, ownership, and conflict, which highlighted the difficulties inherent in conducting such a project.

Ethnography

Ethnography is a complex and multifaceted approach to research. One way to begin to define it may be as

a family of methods involving direct and sustained social contact with agents, and of richly writing up the encounter, respecting, recording, representing at least partly *in its own terms*, the irreducibility of human experience. Ethnography is the most disciplined and deliberate witness-cum-recording of human events. (Willis & Trondman, 2000, p. 5)

Or, as La Pastina (2005, p. 141) puts it, "Ethnographers immerse themselves in a culture to retell the lives of a particular people, narrate the rites and traditions of that people, and to understand and explain their cultural practices." The ethnographic approach is a qualitative research approach that consists of detailed, "thick," in-depth descriptions of everyday life, in an attempt to provide a description and understanding of "culture" or the lived reality of particular groups of people. The term "thick" was coined by anthropologist Clifford Geertz (1973) to refer to descriptions that explain behavior as well as context.

Ethnography uses participant observation or long-term engagement with the field, informal conversations and observations, in-depth interviews, and field journals. Although one can argue that all research approaches exhibit forms of bias in

sample selection, methodology, or analysis, ethnography has become deliberately biased and subjective, and proponents of the methodology engage in high degrees of self-reflexivity, acutely aware of their own position and voice in the research process. "Ethnography has represented a shift from empirical practices of data collection, pushing scholars to introduce non-objective strategies to audience analysis and a greater level of self-reflexivity among researchers" (La Pastina, 2005, p. 139). Following critiques of the methodology as too biased and male-centered, self-reflexivity became a focal point in the early 1970s, driven by feminist anthropologists. This "reflexive turn" led to a different style of writing in the works of James Clifford (1998) and George Marcus (1998), with a direct acknowledgment of ethnography as biased and dependent on the researcher's own subjectivities.

The ethnographic approach to gathering data emerged from the discipline of anthropology. In fact, ethnography cannot be separated from anthropology as an academic practice, which is simply "diverse ways of thinking and writing about culture from a standpoint of participant observation" (Clifford, 1998, p. 9). Traditionally, researchers would spend lengthy amounts of time, up to years, in the field, to research, study, and immerse themselves in the lives of a community or culture other than their own. Bronislaw Malinowski (1922), for example, lived for years among the Trobriand Islanders and wrote expansively about their ceremonial customs, which led to the development of various social theories of culture. Since these communities were often located in geographically (and culturally) distant places, ethnography acquired the reputation of "othering" groups of people, most often ethnic minorities. Colonial administrators used ethnographic methods to collect information to assist them to govern minority groups and to collect artifacts for museums (Field & Fox, 2007; Goh, 2007), adding to the negative associations of the methodology.

In fact, as Murphy and Kraidy (2003, p. 4) have argued, "a growing body of media ethnography has been shaped more by the critique of ethnography's associations with colonialism and Western discourse than by the surprise and productivity of the field encounter." Interestingly, one notable exception to this was Jomo Kenyatta's (1938) study of his own Kikuyu tribe in Kenya, though Kenyatta was mentored by Malinowski himself. It might certainly be the case that "labeling fieldwork an act of colonialism is an obvious overstatement, designed to draw our attention to the ways in which white privilege affects anthropological fieldwork" (Wolf, 1992, p. 5). As Wolf (1992) argues, power differentials in society will always exist and anthropologists must be careful not to take advantage of their power in ways that may disadvantage the people they are studying.

Media Anthropology

The adoption of ethnographic approaches appeared at the same time in a number of disciplines. One might argue that ethnography is theoretically and empirically

central to media studies (La Pastina, 2005), in order to truly understand audiences and their engagement with media products. For media scholars in the United States it arose from a desire to find alternatives to traditional social science research (e.g., surveys) on media effects. Early ethnographic work in the United States was based on an opposition to the positivist paradigm, behavioral science, and the quantitative methodologies that were popular. Later, a more critical orientation explored the politics of representation, raising questions about how ethnographies are constructed and in whose interest (Murphy & Kraidy, 2003).

In her ethnographic work with Japanese women, for example, Darling-Wolf (2003a, 2003b, 2004) conducts long-term participant observation, focus groups, and in-depth interviews to explore these women's conceptions of attractiveness and beauty within the broader context of Japan's relationship with the West. She demonstrates how in their daily consumption of Western media representations of women, Japanese women constantly negotiate cultural, gendered, class, and racial identities. Similarly, exploring audience reactions to telenovelas in rural Brazil, La Pastina (2005) has argued that an ethnographic approach is useful in understanding the complex relationships between viewers and texts, as well as allowing an investigation of reception and appropriation to better understand the role of the local in the process of media engagement. As he concludes:

Ethnography has the potential to observe community and social changes that might be related to media presence, due to its ability to develop longitudinal investigations . . . [and] allows investigators to grapple with the complexity of the relationship between viewers or media consumers and media texts as an ensemble that connects all the available media sources. (La Pastina, 2005, p. 142)

Similarly, Lila Abu-Lughod (2002) has approached the consumption of Egyptian television serials as a mechanism for the production of personal subjectivities.

Historically, journalism research has focused on quantitative approaches such as survey methods and content analysis, and the use of ethnographic methods is a sharp departure from this trend. Parameswaran (2005, p. 205) has argued for cultural studies approaches to the "transformations in the mediated landscape of journalism in many locations across the world, transformations that have profound implications for scholars interested in audience research and popular communication." More critical inquiries into the production and consumption of journalism (and not just popular media) can contribute to the field of audience research (Parameswaran, 2005).

Murphy & Kraidy (2003) argue, however, that media ethnographies have not demonstrated a commitment to immersion or long-term observation, instead relying on in-depth interviews and discussion groups and, in general, a "mostly textual and rhetorical handling of ethnography" (p. 305). Lotz (2000) similarly notes that reception researchers typically conduct a "hit and run" version of participant observation,

not ethnography. La Pastina (2005, p. 147) argues for audience ethnography to be repositioned as a fieldwork-based, long-term practice of data collection and analysis: "Media ethnography needs to return to a sense of commitment to traditional practices; a long-term, in-depth, site-specific, multimethod approach."

Studies such as those conducted by Mankekar (1999), Tufte (2000), and Darling-Wolf (2003a, 2004), among others, do draw on cultural immersion, though, as Murphy and Kraidy (2003, p. 310) point out, studying the relationship between media reception and cultural practice is complex as it requires recognition of the multisited nature of the "field," as well as a need to "address the unique dilemmas of localized research in relation to the global issues raised by transnational media processes." Kraidy and Murphy (2008) advocate an approach drawing strongly on Geertz and the idea of "thick" description as a means for communication studies to realize that contemporary experiences of locality are not distinct, but should be considered within the context of global historical dynamics.

The work of researchers such as Ien Ang (1996), Thomas Lindlof (1987), James Lull (1990), David Morley (1992), and Janice Radway (1984) have dominated the discussion about the qualitative study of audiences and the meaning of ethnography in the field of mass communication research. It was the early reception studies of Ang and others that paved the way for the ethnographic turn in audience research (Fourie, 2001). Many media anthropologies or studies drawing on the methodology of ethnography focus on consumption and audience reception. As Ang (1991, p. 165) writes, "an ethnographic method is "preferable to industry techniques precisely because it holds out the hope of representing consumption practices from the virtual standpoint of actual audiences." The concern with the production of meaning lends itself to this particular methodology. However, much of this kind of work has been based on interviewing people in their homes, with actual immersion in the daily practices and social words of the people studied virtually nonexistent (Spitulnik, 1993).

Fieldwork is challenging in the field of media reception because it is difficult to participate in the closed contexts or private spaces of media consumption, leading to a rethinking of what constitutes "doing fieldwork" (Murphy & Kraidy, 2003). Many early media studies that claimed to be ethnographic research simply consisted of qualitative group and in-depth interviews, and were not conducted in the respondents' natural setting. Moreover, media ethnography "should be understood as a research process of forming communities and making conversations that underscore a systematic and long-term investment in form, purpose and practice" (Murphy & Kraidy, 2003, p. 306). Finally, the very act of speaking for others can be difficult because of the structures of power in which researchers are inevitably implicated (Darling-Wolf, 2003a, 2004). By virtue of their positioning, researchers (explicitly or implicitly) wield power over the groups they study; and they are further affected by power structures related to writing and publication practices, which determine their approaches, as these approaches are dictated by such outcomes.

Case Study: Ethnography of a Local Radio Station

When I was faced with the prospect of deciding on a PhD dissertation topic in 2001, I made a difficult decision: I decided to study what was, in effect, my own community. After having worked for several years at a community radio station in South Africa, as both a volunteer and a full-time staff member, I was keen to make the radio station the subject of my research. Given my extensive involvement in the organization that I was proposing to study, reflexive or narrative ethnography seemed a logical methodological choice. In reflexive ethnographies the researcher's personal background, experiences, and reflections are critical to illuminate the culture under study. Reflexive ethnographies range on a continuum – from starting research from one's own perspective, to confessional ethnographies as described by Van Maanen (1990), where the researcher's stories of doing the research become the main focus (Denzin & Lincoln, 2000).

Wolf (1992, p. 58) advises us to be wary of reflexivity, arguing that

if our ethnographies become polyvocal, somehow managing to portray all the uncertainties, inanities, complexities, and contradictions we encounter in our field research, we may indeed avoid appropriating the experience of our informants, but have we fulfilled the responsibility to our audience?

In addition, Wolf warns that even though postmodernist critique has encouraged more self-reflexivity, feminist researchers should think carefully about whether intense reflexivity might simply be interpreted as being tentative and self-doubting. At the same time though, this does not preclude a reflexive ethnographic approach, for as Darling-Wolf (2003a, p. 169) argues, “no matter how limited and situated our efforts to represent others might be, no matter how partial the truths we uncover . . . the attempt is worthwhile.”

I used traditional ethnographic methods to carry out the research, and Tedlock's (1991) approach of narrative ethnography to incorporate my experiences into the ethnographic description and analysis of Radio X, with the emphasis on the “ethnographic dialogue or encounter” between myself and members of the group being studied (p. 178). Drawing on Deleuze and Guattari's (1987) notion of rhizomes as “grass-like,” heterogeneous entities with multiple entry points and routes rather than roots, I theorized Radio X as a connector and bridging mechanism that impacts the social fabric. The theoretical notion of the rhizome draws on the botanical image of a rhizome as an underground tuber that grows horizontally, in direct opposition to what Deleuze and Guattari call “arboric systems of knowledge” based on the model of a tree, which symbolizes linear thinking and hierarchical structures. The local radio station was thus theorized as a horizontal form of growth – not necessarily successful in comparison to commercial stations whose growth is measured more linearly, but successful in terms of its own horizontal growth and connections. “A

rhizome has no beginning or end; it is always in the middle, between things, interbeing, intermezzo" (Deleuze & Guattari, 1987, p. 21).

The methodology thus consisted primarily of an ethnographic consideration of Radio X, with the researcher as instrument and reflective heuristic device. A qualitative ethnographic approach was essential in order to arrive at a full understanding of the functions of the radio station, particularly with reference to the relationship between political rhetoric around aims of the project and actual practice on the ground.

Anthropologists have generally paid little attention to radio, even though the subaltern populations that are most frequently their subjects usually listen to the radio (O'Connor, 2001). In general, the field of media studies has had an ambiguous relationship with ethnography. Participant observation has been used to study the production of newspapers and TV shows, but cultural studies has been more receptive to ethnographic methods. As a few anthropologists became interested in the use of radio and TV by aboriginal people, there is some overlap between their writing and cultural studies, for example, the work of Eric Michaels (1994) in Australia.

In other words, this study took note of the shift in the 1970s from an emphasis on participant observation to the "observation of participation," and to concerns with power and praxis and the epistemological doubt associated with the crisis of representation (Denzin & Lincoln, 2000). The value in ethnographic methods "lies precisely in their ability to help us 'make things out' in the context of their occurrence – in helping to understand . . . media consumption practices as they are embedded in the context of everyday life" (Murphy, 1999, p. 208). Ethnography sets aside the notion that behavior is rule-governed or motivated by shared values and expectations, and acknowledges that social structures are locally produced, sustained, and experienced (Holstein & Gubrium, 1999). In ethnographic fieldwork, the process of conducting fieldwork involves the cultural biography of researchers and calls for negotiations of power relationships between researchers and people they meet in the field. For feminist ethnographers in particular, rigorous self-reflexivity as a way of interrogating the research process helps to reveal power inequalities that arise in the field due to social constructions of race, gender, and so on (Parameswaran, 2001).

As Huesca (1996) points out in his study of the *reporteros populares* (people's reporters) in Latin America, ethnography is a useful way of explaining how participation is enacted and constructed. Much of the literature on communication, participation, and democracy has been useful for documenting and justifying the move to create more inclusive media systems, but few have pointed out how this participation occurs. This construction of participation is of theoretical and practical importance given the growing interest in revitalizing the relationship between communication, democracy, the public sphere, and social change (Huesca, 1996).

Similarly, Hocheimer (1993) moved beyond merely describing community radio stations, and points out that such media structures should be more closely examined. He notes that inevitable problems need to be addressed where these newly conceptualized media come into being, and as more people start producing information

for themselves. Inherent in the difficulties of attempting to establish and maintain democratic media is the problem of defining “what constitutes a communicative democracy and how to realize one in practice” (Hocheimer, 1993, p. 174). Hocheimer raises other potential problems, such as: (1) whether a station exercises any form of gatekeeping or whether it should be a conduit for all who step before the microphone (or perhaps both); (2) what happens when power, or people become entrenched, and when the interest or agendas of newcomers are at odds with those of the founders; and (3) whether a station functions to serve its constituent community segments and whether the community acts as resources for the station.

These were the very issues I was interested in exploring at Radio X, since intended practices and policies may not always translate into action. In particular, I was interested in exploring the fact that the station always claims to serve what they labeled vaguely as “the community.” This chapter now provides a brief description of the ethnography conducted and, in moments of self-indulgent self-reflexivity, reflects on the process, particularly the outcomes which led to the researcher being excluded from the community studied – a common but infrequently discussed risk.

The Fieldwork

My initial foray into fieldwork took place when I was a novice to both Radio X and ethnography (1995–1999). Fieldwork was carried out while I was working at the station as a producer of an eight-part, 30-minute series dealing with health and social issues relevant to the elderly and aging. I also drew on experiences working at the station as a full-time programmer for two years prior to that, and in a voluntary capacity in earlier years. During these times I presented programs, facilitated training programs, assisted with scheduling, wrote and edited stings and advertisements, assisted with studio technical assistance for some evening programs, and facilitated a training course. The primary data gathering methods during these periods were participant observation and in-depth interviews with permanent and voluntary staff. Fieldwork, thus, comprised a long-term engagement with the station over a period of several years.

Insider/Outsider Dilemmas

While I did not consciously set out to conduct a native ethnography, at some point during my research I realized I was doing exactly that. My knowledge of and interaction with the field had made me part of the field. Denzin and Lincoln (2000) describe native ethnography as third- and fourth-world researchers who share a history of colonialism or subjugation, including subjugation by ethnographers who have made them the subjects of their work. Many students and interns have passed through

Radio X to do research on the station, but the station had never seen the physical products of this work; or their writings were often in languages other than English. These researchers arrived from abroad armed with tape recorders, cameras, and notebooks, then vanished, presumably back to their first-world locations, to write up their notes. It was often the case that neither the notes nor the final products of their academic tourism ever made it back to Radio X. Over the years many visiting students had told Radio X that the organization or some aspect thereof was the subject of their academic research, but the station did not have any copies of these documents.

This raises the issue of the origins of ethnography as a methodology for studying the colonized Other, often replicating the existing *status quo* by reinscribing the continued oppression of groups of people. This increasingly raises issues of who is able to speak on behalf of whom:

As those who used to be the natives have become scholars in their own right, often studying their communities and nations, the lines between participant and observer, friend and stranger, aboriginal and alien are no longer so easily drawn. We now have a notable group of “minority” anthropologists with a range of ambivalent connections to the abandoned and reclaimed “homelands” in which they work. The importance of this “native anthropology” has helped to bring about a fundamental shift – the shift toward viewing identification rather than difference, as the key, defining image of anthropological theory and practice. (Behar, 1996, p. 28)

This also raises issues regarding the audience, or those we study and how we theorize them. Shome (2006) points out that trends in postcolonial theory and transnational cultural studies have changed the way we think about “audience,” “reception,” and “spectatorship” as a homogeneous stable group. “Contemporary conditions of mobilities and immobilities, cultural flows and stasis, produce new hybrid spaces (and practices) of consumption that productively throw into crisis any notion of the audience as being culturally stable and predictable” (Shome, 2006, p. 264). The idea of studying the Other as a culturally stable group, thus needs to be interrogated.

Everyone, particularly management, was enthusiastic when I arrived in June 2002 with the news that I too was making Radio X the subject of my research. The organization seemed to think that finally someone would write something that they could share ownership of. While I was working at the station, a workshop facilitator visiting from the United States brought in an academic article on Radio X that had appeared in an international peer-reviewed media journal. The author had written extensively on Radio X, though he had not visited the station or interviewed any staff. Shortly thereafter, the station director sent an email to several people, including myself, saying that since we had direct access to the organization we should correct this kind of work by writing and publishing in our capacity as Radio X staff or volunteers.

One evening, during a casual conversation after work, one staff member said to me, “I can’t wait to read your thesis.” The station director had said to me on

numerous occasions that I should write a book on Radio X or that my thesis should be published as a book. I was held responsible for telling the story that no one else had told. I was trusted to produce a tangible product from my interviews and observations as no one else had done. At some point during the research, I was motivated by the words, "I can't wait to read your thesis." I kept thinking that if they wanted to read my thesis, I'd have to write it first! Of course my next thought was, "Do I really want them to read my thesis? Will they like what they read?" In the field, ethnographers often find that they cannot fulfill a specific role as insider or outsider. This introduces an increased complexity into the dichotomy, resulting in the embodiment of multiple selves (Darling-Wolf, 2003a). In this instance, I was blurring the roles of both insider and outsider, which raised its own unique sense of power dynamics – in this case the radio station wielded a form of power and control over me, but of course there was also my own embedded power as the researcher and author of their story. "The very structural features of [ethnographers'] discursive practice create problematic power relations between the privileged researcher . . . and her subaltern subject" (Darling-Wolf, 2003a, p. 155).

This raised many ethical issues in terms of how much was disclosed in the final report. When I started the research process I entered Radio X from a very critical perspective, almost certain that they would be unprepared for my inevitable criticisms of the organization. I had had the benefit of three years abroad in graduate school and I returned bursting with ideas about how the organization should be transformed from my new vantage point of theoretical "superiority." However, what I found was something completely different. The more time I spent at the station, the more I struggled to find the flaws. Every single day I spent at Radio X during the research period, I found evidence to support the positive work being done there. This was clearly a manifestation of "going native," a phrase usually used to describe the phenomenon of researchers becoming too closely aligned to their subjects to view matters "objectively" – I could clearly see flaws several years later when I looked back at my field notes. Furthermore, I was determined that my relationship with Radio X would not end when I finished the research. Since I planned to live in the country after graduation, I also planned to return to the organization in a voluntary capacity; and indeed I took up the offer to return to the station full-time in as station manager. As a result, decisions about what to include in the final report became increasingly important, even though I may not have been aware of this at the time.

My dual positionality as insider and outsider, academic researcher and member, was advantageous, yet problematic. Adler and Adler (1994) coined the term "complete member" to refer to this problematic. While no longer employed by the station, I was always introduced to outsiders as an "ex-programmer who is now a volunteer producer." And even though I assumed the relatively demoted title of volunteer producer during the research period, I was still accorded my old role by those in leadership, particularly because the same people were still running the station when I returned. Leaders confided in me about their hopes for and concerns about the

station, and producers frequently elevated me to a position of authority by requesting my help with or advice on their programs.

For me, this meant I had to rethink research practices in more culturally interactive ways, and to be consciously self-reflexive (Hedge, 1998). After all, "research is an expression of our location in a world connected by lines of power and cultural asymmetry," in order to study "counternarratives from global peripheries" (Hedge, 1998, p. 285). Hedge (1998) warns that we should be careful of the notion of indigenous theory and of viewing society as organic or authentic, as this fails to recognize the contradictions and contested nature of culture. The "historical predicament" of ethnography is that it is always caught up in the invention (not the representation) of cultures (Clifford, 1998, p. 2). Hedge (1998) and others have called for transnational inquiry which explores the interstices or the in-between, and thus becomes more than just doing research about the Other or the "authentic native." Instead, the autobiographical position of the researcher is highlighted. In addition, "transnational research requires a progression from uncovering of universals to the representation of contextually specific material practices" (Hedge, 1998, p. 288). Similarly, in her research with Japanese women, Darling-Wolf (2003a) warns against the "essentializing tendencies by Western scholars to search for indigenous traditions and authentic cultural forms in their attempts to represent 'exotic' others" (p. 154). "As ethnographers, we must be prepared to look at culture not as a system enclosed in itself, but rather as a system in continuous motion" (La Pastina, 2005, p. 141).

I found that my rapport with the organization, as the result of having worked there, facilitated interviews considerably. Staff members were briefed on my research during a staff meeting, and everyone was asked to make time for my interviews. I also found that my personal relationships with staff members helped because they were much more open in conversation during the interviews. Even though our conversations were tape-recorded, people appeared comfortable talking with me and frequently referred to shared experiences. Ethnographic rapport refers to building up trust and friendship with respondents in exchange for information, though as Field and Fox (2007) argue, this is disingenuous because of the ulterior motive of an academic career underwritten by the fieldwork.

To some extent this may also have been a limitation, because I found that I had to constantly push interviewees for greater detail. Because they assumed that there was a shared understanding about Radio X, they frequently omitted what they believed to be minor details or facts that they assumed I was already aware of (Jackson, 1987). This was also a personal limitation – that is, because I was already familiar with the organization, I had to guard against asking questions based only on my own experiences there, or my own preconceived understandings of the station, lest they limit my conclusions. It is for this reason that I carried out participant observation during the first few weeks of fieldwork, before drafting interview questions based on notes from these observations. Participant observation was thus used to generate the basic interview questions.

Furthermore, because Radio X has won many awards, staff members are accustomed to being interviewed frequently by the local and international press. The station has even been the site of several films and documentaries, including an internationally produced documentary. I was concerned that this, together with my familiarity with some of the interviewees, could lead to stock positive responses or what Spradley (1979) describes as translation competence, that is, the undesirable tendency of informants to provide prepackaged, party-line, and extra-emic answers to questions (Agar, 1986).

At the same time I think that former and current volunteers were more open with me during interviews because, in their eyes, I was no longer associated with the station. Many volunteers openly expressed their criticisms of the station in ways that they never did with staff members, and would never have with me had I not been perceived as a researcher or, at the very least, an *ex-staff* member. Another issue that arose when conducting interviews was a struggle over the ownership of these interviews. At some point I became involved in a discussion with some staff members about how poorly organized the Radio X archives were and how it was necessary to record a history of the organization. One person suggested that my interviews could fill this gap and that I should make them available to be burned onto CD and kept in the archive for future reference. Another concern someone raised was that many of the people whom I planned to interview may not be alive in the next decade and that their interviews are important pieces of oral history. At first this seemed an excellent idea – a way for me to complete my research and also to give back something concrete to the station, in the form of contributing toward an oral history archive. However, once I actually started the interviews, I quickly changed my mind as I heard material that could be considered confidential. For example, material in which interviewees make personal, potentially harmful comments about each other may not be appropriate for such an archive.

The situation was autoethnographic in the sense that I could not completely distance myself from the research or the ethnography as a distant or objective observer. The autoethnographic experience is neither here nor there, but betwixt and between, since one is simultaneously insider and outsider, native and foreign, standing “in that undeterminable threshold place where she constantly drifts in and out” (Trinh, 1989, p. 418). Occupying the spaces in between also has advantages. As Said writes, “The essential privilege of exile is to have, not just one set of eyes but half a dozen, each of them corresponding to the places you have been” (quoted in Akinde, 1999, p. 48).

Authority and Ownership

In a rhizomatic methodological approach, where the ongoing deconstruction of binary opposites is key, and things are both this and not this (Deleuze & Guattari, 1987), authority and ownership must be deconstructed. Even in so-called participa-

tory research, the voice of the researcher is usually dominant. This hierarchical, arboric approach means that the researcher is always in authority, and ultimately owns the text.

I intended to invert this with my ethnography of Radio X through a rhizomatic approach. I hoped to achieve this by writing a text that would be accessible to the members of Radio X, as opposed to one that excludes the very subjects of the study. Furthermore, the text would be both accessible and available, as opposed to the many researchers who do dissertation research in the developing world and are never heard of there again. The final copy of the thesis was left on a central table in the station's building, a meeting place for informal chats and the spot where everyone took their lunch. After a few days, the printed and bound copy became well thumbed, as it was constantly being leafed through by staff members during their tea or lunch breaks. In addition to the physical hard copy, the thesis was submitted online, and thus available electronically to anyone with a download link and Internet access.

I also intended for the final project to reflect the voices of the people at the station, and to engender a sense of ownership and empowerment. With this in mind, the final text was part academic essay, part narrative journalism, with interviewees' voices constantly present through the use of direct quotes. Privileging interviewees' personal experiences in this way in turn validated the work being done at the station, and hopefully resulted in a sense of collective empowerment. The final project was an academic dissertation, but it is also a live text that reflects the complex interpersonal relationships and the rich visual impressions that constituted the research process, as well as the station itself.

Conflict

And then it all began to unravel, perhaps at the point at which I exited the organization, or perhaps at the point at which I re-entered as station manager. Somehow, somewhere along the line, the organization had taken ownership of me and my dissertation. I could no longer be an independent researcher – I was an embedded researcher (much like an embedded journalist attached to a military unit during armed conflict). While, as mentioned earlier, I found it hard to find the flaws during my dissertation research, they became all too clear to me when I returned as station manager, particularly through the process of trying to get the thesis published or to publish chapters as academic journal articles. One major critique I faced was the writing style of the thesis. While, as mentioned, I had deliberately set out to combine the stylistic features of narrative journalism and academic writing to make it more accessible to a nonacademic audience, this was a limitation in terms of its suitability for publication. There was no pressure to publish (or not to publish) aspects of the thesis, but the benefit of distance allowed me to see the flaws in what I had previously written, and I found myself disagreeing with my own work and questioning my own

initial interpretations as I began to see it in print. At this stage, I also felt as though taking the next step – moving beyond merely vocalizing my critiques to actually putting them down in writing, and publishing this writing, might be seen as an act of betrayal.

Differences in management approaches arise out of diverse or conflicting ideas about the purpose and value of community broadcasting (van Vuuren, 2003). In particular, I came into conflict on many occasions with the station director on this very issue. While we were in agreement that the goal of community broadcasting was to empower the local community, there were disputes as to the exact ways to go about doing this. Furthermore, I believed that the key was to build a sense of agency in the community, and not to treat the community as a vacuous mass, in the classic sender–receiver model. The station director model did not believe that funds should be made available for this purpose. I slowly discovered, to my disappointment, that while the organization had huge promise as a vehicle for participatory communication, it was being held back by the person at its head. The station management had not changed during my tenure at the station, but I had slowly grown more critical as a result of daily interactions, and as a result started noticing these flaws.

Furthermore, I discovered that, while others shared my opinions, they would not support me in meetings because they feared the station director. We were really all puppets on a stage, being controlled by the station director puppet master, and completing an intricate dance for the international funding agencies. Our salaries were constantly cut back; we worked without contracts or benefits; the threat of being fired was constantly dangled before us; and we had absolutely no decision making power. Everything had to be run through the station director.

I also started to realize that an intricate process of exclusion limited access to most individuals. It was ultimately up to the puppet master to decide who was to be employed and who was to go on air. He hired family members who underperformed, and on several occasions used us to fire staff, whom he then summarily rehired, in order to construct his reputation for compassion. While the concept of the public sphere does not necessarily imply equal access for all, I found the control by the station director to be particularly exclusionary.

We had conflictual interactions several times in management meetings, and I eventually tendered my resignation, stating clearly that I was leaving because I did not feel that I had enough room to fully carry out my job as station manager. There appeared to be no hard feelings, and I carried on with my research and writing about the station, my friendships with individuals at the station, and my occasional visits and part-time voluntary production work.

Then one day it all finally unraveled. There was word that the station director was using other staff members to spread a rumor that the organization had “sent” me to graduate school (I was a Fulbright scholar), and that I was repaying this debt by leaving. My staff member friends and informants stopped returning work-related emails and calls, and an agreement to broadcast my students’ radio projects was summarily ignored. I suspect that requesting my framed diploma was certainly a

pivotal point. Faced with the daunting prospect of personalizing an office for the first time in my life, in my new position as a research fellow at a local university, I had called the radio station and asked whether, since I was no longer the manager, I might have my diploma back to display in my office. After several months, and a pointed email from myself to the administrator, I was told that I was now part of the Radio X Hall of Fame and that they would like to keep the diploma. Even upon exit from the organization, they felt the need to wield a sense of ownership because I had once researched them. It is possible that colleagues and friends whom I had interviewed felt betrayed because they had thought of me as “one of them,” and the production of a doctoral thesis together with the title of “Dr” clearly set me apart, even if this was not my intention.

Discussion

I had fully immersed myself in Radio X, a process I found constantly exciting as both researcher and staff member. In negotiating the line between insider and outsider, I found an uneasy space in between the two, from which to understand and interpret what I was seeing. Conducting a native ethnography in your home city, surrounded by friends and colleagues, positions you in a realm very different than the one occupied by the pioneers of anthropological and ethnographic research. Instead, an element of social responsibility comes to the fore as you attempt participatory approaches, try to please your future audience – academic professors, peers, colleagues, and research subjects – and simultaneously attempt to create an academic assignment that is going to be graded, and which might determine your future career.

I conducted the ethnography of Radio X while acknowledging all the while that no blueprint for such a methodology exists, yet creating a product which was both something that selfishly helped me to understand myself and my passion for community radio, as well as a gift that I presented to Radio X, so that they could see themselves as I did – and hopefully this is still as close to a mirror image as anyone can get.

But perhaps it was inevitable that the “natives” would eventually turn against me. After all, one cannot betray one’s friends by turning them into research subjects. Or is it the other way around? Either way, I lost friends and the opportunity to participate in what I still believe to be a truly grassroots medium, despite an autocratic leadership structure. Researchers need to think consciously about how to manage relationships with informants, particularly in terms of negotiating this line between informants and friends. While the relationship will always be tricky, they should remain aware of possible ethical and other implications as these relationships deepen over time. Maintaining a professional distance while building intimate friendships in order to deepen understanding of context is necessary, but potentially difficult; fundamentally, relationships are central to the practice of ethnography.

In fact, the breakdown of the relationship may have been primarily a result of my paternalistic relationship with the station director, and its subsequent breakdown. Perhaps this is where I made the greatest methodological mistake – to set myself up as a researcher and then to follow this by taking a job, a very unusual sequence of events for any anthropologist. Some might say that this was a small price to pay for an award-winning¹ PhD dissertation and the anthropological experience of a lifetime. Dynamics of gender and race also come into play here, and the ethnographic media researcher needs to be aware of how his or her own class, race, and gender might affect research outcomes. In this particular instance, being a black woman was a key factor in the relationship. It was clear that having a black woman station manager with a PhD was important to station management in a national context with few female media managers, and at a radio station with a strong black identity. In addition, this particular radio station had clear gender equity targets, always proudly stating that at least 50% of management staff were always female. As a result, I was always introduced as “Dr Bosch,” and the station director always mentioned my thesis and educational qualifications to visitors.

As Darling-Wolf (2003a, 2004) pointed out in her feminist research with Japanese women, silencing ourselves for fear of criticism could be epistemologically dangerous in its avoidance of political responsibility. In the present instance, my responsibility was to remain true to myself and to be honest and critical with the station director as a researcher and not as an employee. But for future researchers, there remains a valuable lesson never to confuse real life with the research setting. South African radio, particularly community radio, remains under-researched, and ethnography still remains a valuable methodological tool to understand it, despite the challenges one will invariably face. Despite the problems it raises, “the need for ethnography – away and at home – is greater than ever before” (Van Maanen, 1990, p. xi).

NOTE

- 1 The dissertation was awarded the 2003 Broadcast Educational Association (BEA) Kenneth Harwood Outstanding Dissertation Award.

Autoethnography in Media Studies

Digitalization of Television in Finland, or Carrying Home Cardboard Boxes

Johanna Uotinen

ABSTRACT

This chapter discusses the possibilities and limits of autoethnography for media studies. As an example, I use my own technological experiences with television as it relates to the digitalization process of television broadcasting that occurred in Finland. The chapter demonstrates how autoethnography makes it possible to study media-related everyday practices that are difficult to research with other methods, as these practices have become invisible due their repetitive and mundane nature. To conclude, I suggest that autoethnography is a method that offers possibilities for connecting the personal to the cultural and social and thus grasps everyday-based small agency.

Until the late 1980s, it was simple enough to watch the telly: programs were watched when they were broadcasted. Then the videocassette recorder (VCR) was introduced, but as far as I can remember, the biggest challenges had to do with learning how to use the timer, which seems a relatively simple task now, insuring that there is enough room for the timed recordings in the cassettes, and writing down their contents. Gradually, the main problem was not the technology itself but the result of using it. After my hubby and I bought our first VCR sometime at the beginning of 1990s, our cassette

collection started to increase at an accelerating pace. Although we had far-sightedly chosen an advanced model with a half-speed recording mode, which doubled the recording time of the cassettes, it soon began to look like there were cassettes everywhere at home.

It was no wonder that we were excited when the first digital TV-related technology, a recording DVD player with an internal hard disk, became available in Finland around 2005. With such a device, programs that were saved to be watched later would not fill the shelves and cabins, but could amazingly be stored inside the gadget itself. Also, the stuff that one wanted to keep would take up less space, since a DVD disc needs a lot less room than a VCR cassette. Furthermore, with a hard disk, it would be possible to decrease the space needed for the already existing collection, because it allowed the most important VCR recordings to be translated into DVD format. The device simply seemed too good to be true!

Naturally, we had to get a gadget that offers such excellent possibilities. So, in summer 2005 my husband carried home a big cardboard box containing a hard disk–DVD unit, as it was cleverly named in the manual. I remember being slightly nervous about how this new miracle would cooperate with the already existing old TV and the not-so-old VCR. Eventually, it was surprisingly easy to connect the unit to the older devices. The system did what it was supposed to do; the programs got recorded and transferred from the VCR cassettes to the hard disk, and when we wanted to watch the programs from the hard disk or the DVD, we could do so exactly as promised.

The text above is the beginning of an autoethnographical story on how our television gradually turned into a digitalized monster. Autoethnography as a research method had appealed to me for a long time before I actually tried it myself. My reasons for toying with the idea of autoethnography had probably something to do with the fact I had worked for almost 10 years as a project researcher and had done extensive amounts of ethnographic interviews not only for my own research purposes, but also for the interests of the research projects. Thus, I found myself becoming slightly tired of conducting series of interviews, organizing the fieldwork, facing informant after informant, transcribing the interviews, and analyzing the stories told by others: I longed for a change. Moreover, I had always had personal experiences relating to the topics on which I was interviewing, and eventually it began to feel odd that I would always rush to get an interview from someone else when I could answer the questions myself.

However, it was not until the digitalization of television broadcasting in Finland that I was finally encouraged to take the step from merely playing with the idea to actually doing autoethnography in practice – that is, trying to use my own experiences as research material. I began to contemplate my own relationship with television and the changes that had occurred in it by means of autoethnography using concepts such as domestication and agency (Uotinen, 2010a). What I found especially interesting were the links between technology, gendered practices, and agency as well as the fact that autoethnography turned out to be such an excellent tool for making these relationships visible. So I wrote another article on the topic (Uotinen, 2010b).

Doing autoethnography proved somewhat difficult, though. There were plenty of autoethnographical articles, which I read in order to get a grip of the method. The problem was that methodological texts proved to be more rare, and thus I found very little practical advice on how to actually do autoethnography (since then, textbooks have been published, for example, Chang, 2008, and Muncey, 2010). However, I came to the conclusion that there is a good reason for this scarcity: every autoethnographer tends to produce her own personal conceptions and research practices during the research process.

In this chapter my aim is to do autoethnography on autoethnography. I will therefore discuss autoethnography as a research method on the basis of my own experiences. I have already explained how I ended up trying to do it, and in the following pages my goal is to connect the theory to the method in a comprehensive way. I will further utilize my own autoethnographical accounts on the digitalization of television in order to illustrate the points I make. Although I am excited about autoethnography and have found it a useful method, I am not denying the problems and difficulties involved in it, and that is why I will not only discuss the strengths and benefits of the method but also its methodological weaknesses.

Autoethnography

However, there are always problems with new technology. With the hard disk–DVD unit, the problems began when I tried to edit the ads out of the saved programs. The possibility of editing the advertisements out of the recordings was one of the main reasons for our getting the device in the first place. When the shelves and cabins are full of cassettes, there is no point in saving tens or hundreds of hours of reluctantly recorded advertisements. Not to mention the improved comfort of viewing when there would no more be a need for winding past the ads. So expectations were high when I searched the manual to see how the promised editing would actually happen. This was the end of effortless use of the unit. The main reason for the problem was the language of the manual, which was difficult to understand to say the least. Apparently, the text was in my native tongue, Finnish, but as regards the communication of the message, it could as well have been ancient Egyptian written with hieroglyphs.

When I found the passage on editing and tried to produce the anticipated result, something totally different happened. After a longish rereading and reinterpretation process, I realized that in the manual “editing” does not mean what the term usually means, but it means copying files from the hard disk to a DVD and vice versa. The editing that I wanted to do was surprisingly named “creating the playlist.” After these teething problems, however, I managed to absorb the language of the manual, and ever since then the hard disk–DVD unit has done exactly what it was expected to do – especially after I learned to pull its plug from the socket at least once or twice a month. This way the unit’s computer-like nature was brought under control and it would not crash.

Autoethnography is a method in which the researcher's personal life experiences form the starting point and the central material of research (Ellis, 2007). The method is based on the so-called crisis of representation in the field of anthropological research, on discussions that concentrated on the limits and conditions of ethnography and ethnographic knowledge (Spry, 2001). The crisis of representation dealt with the questions of the (power) relations between ethnography, ethnographic writing, and "the Others," the objects of the research. These questions can be traced back to the earlier phases of the discipline – back to times when it was natural and acceptable to regard the researcher as the authority, who could brush aside the fields' multivoiced nature, to use the "objective" and "neutral" voice of science and the ethnographic present tense, as well as to objectify and exoticize informants (see e.g., Atkinson, Coffey, & Delamont, 1999; Clifford, 1986; Clifford & Marcus, 1986; Marcus & Fischer, 1986).

The earlier conventions of ethnographic research and especially writing were questioned, along with the crisis of representation. It was pondered whether it is at all possible to describe the Other's culture and if so, how and on whose conditions? As a result of these discussions, ethnography was no longer seen as describing the researched culture as it is. Furthermore, ethnographic texts were now read not as direct accounts of reality, but as interpretations transmitted by writing. The researcher was no longer seen as an objective observer, but his or her influence on collecting and analyzing the research materials and on reporting the results was acknowledged. Then also the research results were seen as a researcher's personal literary productions, which have their own writing conventions and rules.

Hence the discussions on ethnographic representation laid the foundation for the methods in which the researcher's visibility in both research and reporting became more and more acceptable, and therefore enabled the development of autoethnographic method. Originally, autoethnography referred to the researcher's manner of including autobiographical material in research texts describing the Other. Later the term started to mean a form of research that is (mainly) based on researchers' own life experiences. Now it offers multiple means, such as performative, poetic, and literary tools for the researcher's self-expression (Burnier, 2006; Ellis & Bochner, 2000; Reed-Danahay, 1997).

Autoethnography has become increasingly popular since its emergence in the 1990s. This tendency can be seen, for example, by examining the number of articles published on the topic. I conducted a simple test by searching the abstracts of all Sage journals on the Sage Journals webpage (<http://online.sagepub.com/>) using the keyword "autoethnography" in the advanced search tool box. The result was illuminating. Altogether, 284 journal articles with "autoethnography" mentioned in their abstracts have been published by Sage. Out of those, four came out during the 1990s (the first article was published in 1996: Simpson, 1996), 160 texts were printed in the 2000s, and in the period 2010–2012 120 articles had been published. So it is clear that autoethnography is not a passing fad or a curiosity among a small circle of enthusiasts, but a mainstreaming method in the ascendant.

The interpretation I find most helpful is to think of autoethnography as a type of autobiographical writing and a research method that *connects the personal to the cultural and social* (Ellis & Bochner, 2000). Thus, autoethnography is a research method and text that describes the writer's personal experiences and places those experiences in their social and cultural context. It aims to understand the general by studying the private and individual. This is possible, since a person's life is not merely unique, but also generalizable (Ellis & Bochner, 2000; Reed-Danahay, 1997).

Viewed this way, autoethnography comes close to the idea of *situated knowledge* (Ellis & Bochner, 2000). The concept of situated knowledge (Haraway, 1991) is used to emphasize the contextual nature of all knowledge: knowledge is always connected to a certain time, place, situation, and above all certain people. By situating the study in a certain person's (or persons') everyday experiences, understandings, and practices, by having these as the starting point and basis of the study, it is possible to achieve more general relations and meanings. In autoethnography, the situated knower is the researcher herself, and the other informants do not necessarily exist at all.

The concept of situated knowledge also links autoethnography to gender studies and certain feminist theories. One example of these is feminist cultural studies of technology (Lykke, 2008; McNeil, 2007), in which three relatively new interdisciplinary branches of research – gender studies, technology studies and cultural studies – intertwine (McNeil, 2007). The main idea of gender-sensitive cultural studies of technology is that gender and technologies are produced together in the signifying processes and thus affect each other. Thus, both technologies and the work and skills connected to them are gendered to the smallest piece of knowledge and practice (Faulkner, 2001; Wajcman, 2004). These ideas are also relevant in media studies because there is no media without technology, and therefore both media and its use can be seen as gendered to the core. Furthermore, gender is not the only relevant difference to be acknowledged but ethnicity, age, education, and class, for example, should also be taken into account when appropriate.

However, raw autoethnographic data alone is not enough to develop high-quality research, and it would be unjustified to demand that it does so (see Miller, 1991). Instead of relying on mere raw autoethnographic autobiography, research should seek possibilities for more subtle and multifaceted positions (Ellis & Bochner, 2000). When one is doing autoethnography, the most crucial point, in my opinion, is to carefully situate the research process and the produced knowledge – not only to write texts based on personal experiences, but also to position the study and oneself in the spirit of situated knowledge. This way research is based on a conscious and reflected position in a certain place and situation from where the researcher makes observations and does her work, and the knowledge that is produced is contextualized. In order to see and understand, one must be located somewhere – and this concerns the researcher as an informant as much as those who read the research report (Haraway, 1991).

The Problems of Autoethnography

My hubby and I were so irritated with the whole digi-business going on in Finland in the early 2000s that we had agreed that we would not get a digibox until we were forced to do so. The fact that our flat had a cable connection made our resistance easy, because it meant that we could watch the basic channels without the digibox. That we had to do without certain channels, which were available only digitally, was a bit of a problem at first, but then we stopped reading the program information from the newspaper. Thus, we led a happy analogue life until the summer of 2006. Before that I had been unemployed for a while, which is not uncommon for a researcher in Finland, but then I managed to get a three-month assignment for the summer. Because digital receivers were somewhat expensive, we decided that we should purchase one during my work period, although it was a year ahead of our schedule (at that time analogue broadcasting was supposed to end in August 2007, but later it was decided that it would continue on the cable network until March 2008).

To purchase a digibox was a serious business, and so I began to carefully study what sort of a device would be suitable for us. This was soon over. Since we needed a box for a cable household with a hard disk and two tuners (for watching one channel and recording two others), there were exactly two models available at the time and the decision was easy to make. Consequently, my hubby carried yet another cardboard box home in July 2006. I remembered how easy it had been to connect the hard disk–DVD unit to the TV and VCR and therefore anticipated – despite the stories I had heard – similar ease with the digibox. I was so wrong, so very wrong. The task was so difficult that I had to visit the digibox shop twice for advice and make a phone call to the importer! Both were actions I had *never* taken before for *any* technical gadget. With the installation process of the digital receiver, my technological self-confidence got its first (but hardly last) serious blow.

Autoethnography is not just a way of knowing and achieving knowledge, but it also creates a research text in the way ethnography in general does (see Van Maanen, 1995). However, the main aim of autoethnographic writing is to break the writing conventions of traditional realistic ethnography. This aim is pursued by using, for example, literary and performative means (e.g., Boylorn, 2006; Denzin, 2005; Kaufmann, 2005; Spry, 2001). Therefore, strict demands are set on autoethnography: it should be personal and research-like, evocative and analytic, descriptive and theoretical all at the same time. Autoethnography should also have artistic quality, regardless of whether or not it takes the written or performative form. In addition, it has been mentioned that autoethnographic research should aim at offering care and support as well as producing change in the world and people. All this sets great – even impossible – demands for autoethnographers. It is not enough to be a capable researcher and scientific writer, but societal influence, literary talent, and even acting skills (in the case of performative autoethnography) are also required (Burnier, 2006; Ellis, 2007; Ellis & Bochner, 2000, 2006; Spry, 2001).

According to the autoethnographic canon, the researcher should describe his or her own experiences and emotions in such a way that the description touches the reader deeply and genuinely. Consequently, it has been considered as central for successful autoethnography that the description arouses similar emotions in the reader as the researcher has felt in the described situation. It is this *evocativeness*, the aim to arouse feelings, that separates autoethnography from other forms of ethnographic research (Ellis & Bochner, 2006; Reed-Danahay, 2001).

It is probably because of this demand that very difficult themes such as illness, death, racism, incest, violence, and problematic family relations have been popular in autoethnographic research (e.g., Brooks, 2011; Davis, 2009; Day, 2010; Eicher-Catt, 2004; Elizabeth, 2008; Ellis & Bochner, 1992; Ettore, 2005; Jago, 2006; Lee, 2006; Minge, 2007; Ronai, 1995, 1996; Weaver-Hightower, 2012). The problem-oriented nature of autoethnography is understandable, since more intense emotions – grief, despair, and anger – are probably easier to mediate in a text than milder feelings. However, the prevailing dramatic content gave the impression (at least, to me) that there is no point in doing autoethnography if everything is fine. This impression was strengthened by the fact that the objectives and research nature of some autoethnographic texts that are concerned with ordinary, everyday life experiences I managed to find – for example, watching television – were somewhat difficult to comprehend too (see Ott, 2007; Scott-Hoy, 2003).

The type of research that appeals to readers' feelings, aiming to arouse them, has understandably been criticized for concentrating too heavily on the researcher's personal problems and misfortunes (Anderson, 2006). An approach like this tends to make research either difficult to comprehend, or even awkward and embarrassing, and its relevance could be questioned (Walford, 2004). As justification for the approach, one has offered, for example, writers' empowerment (Ellis & Bochner, 2000). Writing about one's vicissitudes can be therapeutic – but does it need to be research? For me the greatest problem of autoethnography is the manner in which it concentrates *only* on the researcher's experiences. When all contextualization is neglected, this weakens the intelligibility and general interest of many studies regardless of how skillfully they are written.

Furthermore, when all misfortunes and intimate facts are discussed in detail, the reader's feelings might be aroused, but the question is: Are the feelings aroused the "right" ones? For me at least, reading genuinely evocative texts tends to be a somewhat awkward experience, which makes me wonder: Do I really want to know all these private, intimate, and even embarrassing facts the writer has exposed? Since discomfort and awkwardness are not the feelings texts usually aim to arouse, my reaction questions the basis of evocative autoethnography – the idea that the text should be able to transmit and arouse the feeling it describes (Ahmed, 2004).

Thus, the evocativeness is problematic, not only because of its practical consequences, but also from the perspective of situated knowledge and the critique of universal experience (see Skeggs, 1995). In autoethnography both experience and

feelings tend to be seen as undeniable, universal, and transmittable. The researcher's experiences are supposed to be so general that it is possible not only to understand but also to experience them in the same way regardless of the audience's situatedness. This attitude may appear somewhat arrogant, since autoethnographers are convinced of the importance of their experiences to research (Miller, 2008). In fact, it results in a way of thinking that annoyingly resembles the *God-tricks* – relativism and universalism – that aim to hide the subjectivity and situated nature of the knowledge Donna Haraway (1991) criticizes.

The Benefits of Autoethnography

The TV–VCR–hard disk–DVD unit–digibox combination in our TV cabin proved to be a digitalized monster. I had to update it, nurse it, and please it, and still there was no certainty that it would do what I wanted it to do. There were problems with texts, recording, sound, and file transfer – in fact, with almost everything that one can think of. However, after using the system for a while and after some improvement in the quality of the digitalized broadcasting, the basic acts of saving, watching, and deleting the programs began to run smoothly enough.

Yet the case was totally different with the files that we wanted to keep in the DVD format. Those have to be saved on the digibox's hard disk first and then transferred to the hard disk–DVD unit in real time. The difficulties culminated in the fact that, in spite of two tuners, the digibox could not be touched during the transfer or the whole thing would jumble up. This meant that we could not watch anything else but the transferred program during the procedure that actually took as long as the length of the transferred program. After a successful transfer the programs had to be edited so that they could be saved on the DVD discs without ads and other extra bits. All this took more time than ever before and the so-called technological progress in no way decreased the time required for the act of saving the TV programs. On the contrary, it led to a situation where I spent more and more time with the television, but less and less time actually watching it for entertainment.

Why would autoethnography be worth doing if it is so contradictory? According to my own practice-based experiences, there are (at least) five good reasons for trying autoethnography. First, autoethnography offers tools for research that follow the idea of situated knowledge. As it is regarded as an acceptable starting point for research to position oneself in someone else's situation in order to gain situated knowledge (Haraway, 1991), research based on a researcher's personal position and commitments must be justified and acceptable as well. If researchers are unable to describe their starting points in a way that justifies their autoethnographic approach, how could they describe the starting points any better when they do research on others?

It is an increasingly recognized and recommended basis for research that researchers acknowledge the fact that knowledge is situated and committed. This emphasizes

the idea that research results are reliable and understandable only when the knowledge's contextuality – the conditions and situations affecting both informants and researcher in the process of knowledge production – is taken into account. Acknowledging these conditions justifies the analytic move between the individual and the general that is essential in legitimating autoethnography.

Autoethnography further offers possibilities for researching groups, life situations, or experiences that easily tend to remain hidden in research. For example, the gendered nature of media technologies and habits connected to them is so deeply embedded in our cultural understandings – it is so natural and unquestionable – that it goes unnoticed. Autoethnography provides a useful tool to more consciously explore how this process of gendering takes place in everyday life in often subtle ways and “private” contexts.

The implementation of the idea of situated and committed knowledge is, however, challenging in practice: research often results in pieces of general observation from the informants' life situations, which remain scattered and separate, although they are supposed to be contextualizing. Autoethnography offers a possible solution to this problem for the simple reason that it is easier to reach precision in contemplating one's own life than it is when one is trying to describe and situate the positions of others. This means that autoethnography offers a means to pursue situatedness and commitment and to avoid the oversimplification that otherwise threatens when trying to describe the life contexts of other people in relation to the goals of the research.

Second, autoethnography makes it possible to follow everyday life practices. Such practices are, naturally, at the core of ethnographic research in general as well. However, it is relatively difficult to study them with, for example, interviews. The reason for this difficulty is the fact that many mundane habits and tasks are so frequent that they have become invisible. How many of us pay attention to fixed habits and choices that are related to, for example, cooking, computer use, or television watching? As such, these practices are difficult to verbalize, even if the researcher is able to ask the relevant questions. In addition to interviews, observation is another method typically found in traditional ethnography. With observation it is possible to follow what people do, but to find out *why* they do what they do and what are the meanings of the doings, pure observation might not be enough. So it is often necessary to ask for further explanations and clarifications from the informants. Thus, the problem mentioned above of verbalizing the practices might concern observation too.

Autoethnography offers one kind of solution to these problems, because it is easier to concentrate on the details of one's own everyday life. There is also at least one less level of signification: one's own acts, motives, and understandings are probably more understandable than somebody else's explanations of his or her everyday life practices and their contexts. For example, I learned entirely new aspects of my television-related behavior and my choices concerning it when I proceeded to do autoethnography on the topic. Had I done traditional ethnography with informants,

the results might have been interesting, but I doubt I could have attained the same kind of precision that autoethnography enables. This way of doing research naturally requires concentration and honesty, but when it is conducted in a careful and thorough way, autoethnography offers the possibility to achieve delicate understandings and to connect everyday practices (the individual) and social and cultural structures (the general).

The third benefit is the utilization of the researcher's own experience-based knowledge. It is quite possible that, on certain topics, the researcher himself or herself could provide more powerful and relevant information than other informants could. This is the case especially with research topics that may be difficult to access from the outside or that are out of the line of research in general. Furthermore, even when the research theme is not so intimate or otherwise demanding that it would make it difficult to find informants – as is the case with television – it might be possible to gain *thicker* descriptions with autoethnography (on the concept of thick description, see Geertz, 1993). My engagement with autoethnography showed that it was possible to conduct convincing research that was ethnographic in nature while employing other methods than observation and interviews.

One must, however, be particularly critical about research topics, and choices must be carefully justified: credible autoethnography is not possible on any topic whatsoever. In my case, for example, digital television and my engagement with certain health technologies proved to be convincing research themes, since television is one of the technologies that influence my everyday life practices and health technology has also become part of my life experiences (Uotinen, 2011).

When doing autoethnography, the researcher puts himself or herself and his or her personal credibility at risk, not only as a researcher but also as a person. That is why it is particularly important in autoethnography to put special emphasis on the choice of research topic: it must not only be valid in the sense of researcher's experiences but also be theoretically and methodologically justifiable. In the end, the validity of the topic is demonstrated through self-reflexivity when conducting the research, and by following justified, ethical, and transparent research practices.

Fourth, autoethnography offers the opportunity to conduct research when a wider ethnographic fieldwork cannot be accessed due to lack of time, funds, or other resources. The resources for research tend to be scarce, and thus autoethnography might offer solutions to address topics that otherwise would have been neglected. Lack of resources or other purely convenient reasons should *never*, however, be the main argument for choosing autoethnography. The choice has to be done consciously and there has to be convincing research-based, theoretical, and methodological reasons for the use of the method or the result will be unjustifiable.

The fifth benefit of autoethnography is that it is the researcher's own life, not someone else's, that is under consideration and exposed to criticism. When research is conducted in cooperation with the informants, the aim naturally is to follow practices that are as ethical as possible and to have as equal relations between the researcher and the informants as possible, but the researcher still has the last word.

So, there is always the risk of the researcher harming the participants unintentionally (Plummer, 2001). Of course, these ethical concerns do not mean that other people should not be involved in the research as informants at all for fear of “doing something wrong.” The choice must, again, be based on the aims of the research itself: Is autoethnography able to offer answers to research questions or are interviews and/or observation more reasonable solutions?

If autoethnography is revealed to be a valid method for researching a certain topic, the ethical risks are slightly different in comparison to traditional ethnographic research. One does not need to exercise caution with oneself as with other people. Thus, it is possible to deal with questions that could not be otherwise discussed. It is also possible to write in a style that would be regarded as dubious outside the genre of autoethnography. For example, when I write on my television relationship I can freely aim at a somewhat (self-)ironic style, whereas it would not be proper to write about other people using a similar style. However, the limits and practices need to be carefully considered in autoethnography as well, especially regarding other people who may become involved in the study, such as those closest to the researcher. Exposing oneself is acceptable, but to do the same to one’s friends and relatives involves ethical considerations (Ellis, 2007; Skeggs, 1995).

Connecting the Individual to the Cultural: Digitalization of TV in Finland

Eventually I got so frustrated with the complicated DVD recording process that I tried to find out how files could be transferred more efficiently. The supposed answer was that I should do it via a laptop, on which the DVDs can be burned faster. After some searching, I found guidelines for doing the trick on the Internet. It took some pondering and a few attempts, but finally I succeeded in installing the necessary programs both on the laptop and on the digibox. However, in spite of the guidelines and the necessary programs, the files did not jump from the digibox to the laptop just like that. Every transfer took at least a few attempts, and whenever I succeeded, the process was still exasperatingly slow.

The slowness ceased to irritate me when it dawned on me exactly how complicated it was to produce a functioning DVD with the laptop. It would require, among other things, burning the texts into the program itself, converting the file into a DVD-compatible format and then burning it onto a DVD disc. Each of those operations needed a combination of programs that agree to cooperate with the current file, the laptop, and the DVD player. When I reached this point, I discovered that I didn’t have the patience to do all this. I was forced to admit that the technology of our TV cabin was at the point where it was out of my reach, beyond my patience, and probably also beyond the limits of my technical skills.

The toilsomeness of making DVDs resulted in the fact that the hard disks of both the digibox and the hard disk–DVD unit were constantly full to repletion. Because of

this I had to keep making new DVDs so that I could fit all the programs on the digibox hard disk that had been marked in the TV guide to be saved, although the job was so repugnant. And so, little by little and without me noticing it, the monster in the TV cabin started to succumb to my will. It was not exactly fun to use, but more often than not the result began to be what it was supposed to be. And that is how surprisingly many years went by . . . Until in spring 2011 the hard disk–DVD unit that had served well for the previous six years ceased to close the discs it had burned. This was somewhat of a problem, since an unclosed DVD does not necessarily function in any other DVD player. Consequently, it is not very clever to produce tens and hundreds of DVDs that are playable only in an overaged device that could pop off for good any day. So the time had come to find a successor for the unit.

I have included the story of the digitalization process of our TV in this chapter, as it is a good example of how it is possible to intertwine the general and the individual in a way that tells something about the present, as autoethnography should do. The digitalization of television broadcasting was a long and somewhat complicated process in Finland. The first digital programs were broadcast as early as August 2001. The first digital receivers, however, were available only four months later. Furthermore, it was not until August 2005 that the digital network covered most of the country – four years after digital broadcasting had begun. There are still some very remote spots where digital broadcasts are difficult to receive without expensive special arrangements. The date on which analogue broadcasting was to end was also changed several times during the digitalization process. Eventually, broadcasting was digitalized in two waves, in August 2007 (aerial broadcasting) and March 2008 (cable broadcasting). So, the digitalization process began slowly and its continuation was vague, although digital television was an important part of the government's information society policy. The aim was to be at the cutting edge of digitalization in Europe as with the earlier development of the information society (see Castells & Himanen, 2002).

The process included some exaggerated promises of technical advancement, which were not realized. For example at the beginning of the digitalization process there were promises about interactive services among others, but these were all quietly dropped as the process continued. Furthermore, at the beginning of digitalized television there were complications because of unequal visibility, poor digital receiver supply on the market, severe technological teething problems (e.g., subtitles), and, above all, the top-down style of execution of the whole process. Therefore, Finns in general were not at all happy with digital television at first. Now, more than 10 years after the beginning of the digi-TV process, the situation has stabilized somewhat as the worst technical and other teething problems are over.

Still, the digitalization process produced substantial changes for Finland's television field. For example, statistics published on September 3, 2008, show that 98% of households with television had a digital receiver in August 2008. The same statistics, however, also show that just before the final digitalization, there were only 6% of households with no television at all, whereas after the change 10% of Finland's 2.5

million households no longer had a TV. During the previous year and after the end of analogue broadcasting, as many as 100,000 households had given up television. The trend has continued: according to the December 2011 statistics, 88% of Finnish households own a television – and 12% do not. The novelty is the number of households – 15% – that watch television broadcasts via a computer. This was such a rare possibility in 2008 that it was not even mentioned. Thus, the statistics show fundamental changes in the ways Finns watch television that have taken place during and after the digitalization process (Statistics Finland, 2008, 2011).

Experiences in the digitalization of television are especially interesting because of their collective nature. Since the beginning of digital broadcasting, the majority of Finns have faced cracks in their TV-related everyday life practices. Therefore, anyone who complained about digital TV belonged to the mass who even had a language of their own: *digi-complaint* discourse. This discourse appeared on Internet chat-rooms, in letters to the editor, and in everyday discussions. So, the digitalization of television led to a collective experience backed up by individual experiences.

This shows that I was by no means alone with my digitalization-related feelings of irritation and reluctance. So I can assume that my personal experiences were generally representative of the broader social and cultural situation in Finland at the time. Especially because the change from analogue to digital television affected practically everyone in Finland, it is quite probable that I have managed to write about something that touches many other people. It is exactly this argument that justifies my use of the autoethnographical method when researching the digitalization process of television in Finland. Consequently the autoethnography consists of not only my autobiographical descriptions but also the analysis of television's digitalization and even the self-reflexive assessment of the research process and its results.

Small Is Beautiful

Since we had been fairly happy with our hard disk–DVD unit, my hubby and I decided that we had to replace the broken device with a corresponding one. Sure, there were plenty of novelties on the market, such as Blu-ray players, but we never even considered them – especially as changing to a Blu-ray device would have required a whole new television set with an HDMI connector, a must-have for a Blu-ray gadget. The new telly, in its turn, would have not fit into our TV cabinet and refurnishing the whole living room was not worthwhile just for a piece of newer technology. So, our choice was a recording DVD player with a hard disk. I first visited the website of the old gadget's manufacturer and instantly found out that a similar appliance was no longer available. In fact, there were no recording DVD players on offer at all. Luckily a couple of other producers still had the desired device in their range of goods. I wrote down the information on the available machines and we went shopping for home entertainment electronics.

After the fifth store we visited, it began to look highly unlikely that our unit would ever get a successor. In some stores, the salesperson did not even recognize the thing we were trying to buy but calmly insisted that such a device had never existed or that their store had never offered anything like it. In the rest of the shops, the personnel at least happened to know what we were aiming to purchase. Still, we could not get the device, since what we wanted to buy was so *old-fashioned* that it was no longer in the selection. So, in just few years we had fallen from the height of technical excellence to the bottom of the heap.

Finally, we managed to find a store whose seller was interested in making further inquiries instead of just saying no can do. It occurred to us that it was possible to order one of the two similar, still existing devices, although it was not part of the store's basic selection. We made the order and began waiting, but nothing happened for several weeks. Eventually I made some inquiries for the successor to our unit. It turned out that our order had disappeared into the depths of the store's data system and had never been processed. All we could do was to try again. This time we got what we had expected and after waiting for just a couple of weeks my hubby carried yet another cardboard box to our home in June 2011. Unwrapping the package of the DVD recorder unit was a *déjà vu* experience. A similar, more or less agonizing learning process, as with all the earlier gadgets, was about to begin all over again . . .

In my opinion, the problems that are inherent to autoethnography can best be avoided by doing research on topics that are not dramatic but instead describe the researcher's everyday life practices, as I have suggested in my articles on digital television (Uotinen, 2010a, 2010b). However, I do recognize and admit the difference between the type of autoethnography that concentrates on everyday practices and the evocative autoethnography that deals with deep emotions. Consequently, I regard myself as practicing *small* autoethnography (see Rambo, 2007). By small autoethnography I mean autoethnographic research that especially concentrates on everyday, ordinary, "small" themes, whereas "big" autoethnography deals evocatively with the dramatic turning points of life.

I chose the term "small" in order to emphasize small autoethnography's pivotal connection to the concept of *small agency*: the advantage of small autoethnography is that it offers a possibility to study specifically small agency. Small agency is a concept developed by Marja-Liisa Honkasalo and it refers to the everyday agency that is labeled by invisibility. Honkasalo (2006, p. 103) points out how small agency is "characterized by *repetition* and *conventionality*, small movements, unchangeable rhythms, non-unexpectedness of its outcomes, returning the same and so-called invisibility at the same places." Small agency exists especially in the domestic sphere – for example, within housework, and thus is heavily gendered in nature. However, it is not mere monotonous repetition, but it also offers space for holding onto the world, doing things differently, coming up with creative solutions and change (Honkasalo, 2008, 2009). All this means that autoethnography is a suitable tool for approaching small agency.

Generally speaking, agency has become a central concept in the fields of cultural studies, gender studies, and cultural studies of technology and media, to name a few examples. It offers possibilities to conceptualize the interfaces and relations between people's life, culture, and society – and therefore suits well the principles of autoethnography. The starting point of my understanding on agency is Laura Ahearn's (2001, p. 112) definition: "agency refers to the socioculturally mediated capacity to act."

Agency is produced in everyday practices where people negotiate and try to act in harmony with the surrounding society and culture and with the expectations and demands set by them. Understanding agency requires that one analyze not only the practices but also the differences. The differences, such as gender, age, ethnicity, class, education, and even location, have effects on and in agency (Lister, 2003; McNay, 2000). What is especially interesting in the concept of agency is the possibility it offers for discussing temporality, changes, resistance, and even creativity in spite of the outlining social and cultural practices and structures (Ahearn, 2001; Certeau, 1988; McNay, 2003). Thus, autoethnography as a method correlates well with the concept of agency and especially small agency.

In addition to agency in general, it is also possible to concentrate on, for example, media and media technology-related agencies: how media and relevant technologies are made part of our existence and how they become part of our existence. Here the concept of small agency is particularly useful, as the practices connected to media tend to be especially routinized and are thus invisible due to their plain repetitiveness – as my own pondering on the use of digitalizing TV shows. For example, the housework-like, repetitive nature of digitalized everyday life would have remained unnoticed without autoethnographic means (Uotinen, 2010b; see also Cowan, 1985).

What could then be the criteria for high-quality (small) autoethnography? In my opinion, the same criteria that apply to ethnography in general. The knowledge produced by autoethnography is based on the same starting points that are used in more traditional ethnography as well. *All* ethnographic knowledge is subjective, context-bound, and partial; it is committed to the personal perspectives and starting points of the researchers, readers (and informants), and has to be accepted – or rejected – as such (Clifford, 1986; see also Medford, 2006).

It is of utmost importance that autoethnographic research be theoretically informed. A theoretically solid starting point is the premise for formulating research questions. Explicit research questions, on the other hand, form the conditions that enable the autoethnographer to locate and analyze from everything that she remembers those particular experiences that are linked to the research topic. Without clear theoretical starting points and research questions, autoethnography easily becomes something that could well be described as accidental roaming in one's own reminiscences. Therefore it is important to understand what and why one is studying before taking any action – this naturally concerns any research but is even more important in the case of autoethnography. For research credibility, it is necessary to take these

notions into account in situations in which the researcher produces both the materials and the interpretations.

The credibility of (auto)ethnographic research is based on the whole concept and process of the research: the critical choice of research themes, the careful description of starting points and positions, the self-reflexivity of research, the density of research reports, and the fact that social and cultural contexts and connections are created and baselines offered. The most crucial aspect of sustainable (small) autoethnography is to make sure that research does not merely describe the private, but that it also consciously produces connections to the general, social, and cultural. This way autoethnography – instead of being just a hermetic self-report of the researcher – offers possibilities for making observations and interpretations on everyday life that other people can find interesting as well.

The Basics of Experimental Research in Media Studies

Glenn Leshner

ABSTRACT

This chapter discusses the basics of experimental design used in media studies research. Many scientific researchers believe, with good reason, that the controlled experiment is perhaps the best research method for determining a cause and effect relationship between variables. The chapter considers the types of research questions experiments can address, how the experiment can demonstrate causal relationships between variables, common experimental designs, data collection and interpretation, and ethical considerations. A major part of the chapter deals with internal validity pitfalls, such as confounds, randomization, and how to determine acceptable sample sizes. It also considers what may be regarded as controversial issues in experimental research, such as generalizability (or lack thereof), how to create treatment variance, the issues involved with creating message variance, and handling the issues of design complexity and manipulation checks.

This chapter discusses the basics of experimental design used in media studies research. Many scientific researchers believe, with good reason, that the controlled experiment is perhaps the best research method for determining a cause and effect relationship between variables. And yet, experimental research is relatively rare in mass communication studies, especially compared to other quantitative methods such as surveys and content analyses. Thorson, Wicks, and Leshner (2012) report that only 12% of social scientific manuscripts submitted to *Journalism & Mass Communication Quarterly* in 2008–2009 were based on experiments. (2003) reported only 9% to 13% of studies in mass communication use experimental methods. Given that most of the theories in scientific mass communication research involve some sort of causal relationships between variables, why is the controlled experiment so rarely used as a research methodology? There are likely many reasons why this is the case, including the perception that controlled experiments are difficult to do well. Another may rest on misconceptions some in our field have about several key issues that must be considered and resolved when conducting experiments. This chapter is designed to address both of these concerns.

The chapter considers the types of research questions experiments can address, how experiments can demonstrate causal relationships between variables, and common experimental designs. A major component of this examination relates to internal validity pitfalls – such as confounds, randomization, and how to determine acceptable sample sizes – which are discussed in detail. The chapter also reflects on what some would consider more controversial issues in experimental research, such as generalizability (or lack thereof), how to create treatment variance, the issues involved with creating message variance, and manipulation checks. The ultimate goal here is to help students conduct controlled experiments that contribute to our understanding of mass communication processes and effects.

Before discussing the particulars of controlled experiments, it is important to note that a student attempting to conduct an experiment in the absence of compelling theory is likely to become frustrated, if not confused, during the process. The activity of designing and executing a controlled experiment involves many decisions, each with its own trade-offs. The benefits of having a carefully developed theory to help guide the process cannot be overstated. Many, if not most, decisions that need to be made – including those having to do with stimuli design, controls, samples, and so on – can be shaped, either directly or indirectly, by the theory the researcher seeks to inform.

Logic of the Controlled Experiment

The philosophy of the experimental method is to determine cause and effect relationships between two or more variables and to eliminate all possible alternative explanations for the relationship. How is this accomplished? Controlled experiments require three elements that generally are not a part of other research methods: (1) manipulation of an independent variable, (2) random assignment to condition (sometimes called “treatment”), and (3) strong control of sources of variation in the dependent variable that are not due to the manipulation.

A *manipulation* is an independent variable in which the researcher creates the variance (or levels) of the variable. In media studies, a manipulated independent variable is often operationalized as media that vary on particular characteristics. For example, Grabe and Samson (2011) were interested in how participants would evaluate and

remember what they called “anchor grooming.” For their experiment, they created two versions of a TV newscast with a female anchor – one that was “sexualized” and one that was “unsexualized.” The sexualized condition showed the anchor in a tight-fitting jacket and skirt, wearing bright red lipstick and a necklace. The unsexualized condition showed the anchor in a loose-fitting jacket and skirt, wearing no lipstick and no necklace.

Random assignment to a condition (also called *randomization*) is the process of randomly assigning participants to treatment groups (or randomly assigning treatments to participants). Random assignment to condition eliminates the influences of extraneous variables, such as individual differences between participants. In the above study, Grabe and Samson randomly assigned their participants to one of the two “anchor grooming” conditions.

Controlling other sources of variation helps to insure that the cause of differences observed in the dependent variables is due to the manipulation and not to anything else. In their study, Grabe and Samson created two versions of the newscast in which everything was the same across the two conditions except for the manipulation. Also, participants followed the same procedures. Some scholars require that controlled experiments include a theory that convincingly explains the relationships between variables found in the research. Although this last point is not unique to controlled experiments, the lack of a suitable theory that explains the relationships between variables greatly limits the usefulness of the research findings, and thus devalues the research itself.

The manipulation of the independent variable, randomization, and the controlling of other sources of variance are requirements for *establishing causal relationships*. In order to argue that an independent variable caused change in dependent variables, the independent and dependent variables must covary. That is, changes in the value of an independent variable must vary along with changes in a dependent variable. In addition, temporal precedence must be established. That is, the independent variable must precede the dependent variable in time. The manipulation helps the researcher set up a time order where changes in the independent variable occur prior to measurement of the dependent variable. This helps to eliminate the alternative explanation that changes in the dependent variable caused changes in the independent variable. Randomization is crucial to reduce the likelihood that individual differences between participants caused changes in the dependent variable.

Strong controls help to eliminate alternative explanations in that they reduce confounds in your design. The ability to eliminate alternative explanations in cause and effect relationships is called *internal validity*. Well-executed controlled experiments are high in internal validity. However, because experiments often occur in artificial contexts, because the contexts are under the control of the researcher, and because convenience samples of participants are often used, controlled experiments are said to lack *external validity*. That is, the results of experiments cannot be easily generalized to larger populations because their samples are rarely, if ever, drawn randomly.

Establishing Causality

At the heart of an experiment's effectiveness for discovering causal relationships is the control of events in order to eliminate alternative explanations for any observed covariation between the independent variable and the dependent variable. As noted above, this is done by detecting covariation between the independent variable and the dependent variable, by manipulating an independent variable, by randomly assigning participants to condition, and by including strong controls. All of these must be present in order to infer a casual relationship between an independent and dependent variable in an experiment.

We detect covariation between independent and dependent variables by examining statistical relationships between the two. If an independent variable and a dependent variable do not covary, then the independent variable cannot be the cause of changes in values of the dependent variable.

Much of the time, effort, and money researchers spend on experimental research are directed toward the creation of a suitable manipulation. In media studies, this often means systematically varying properties of media messages, media contexts, or media technologies. Depending on the independent variable of interest, creating a treatment that manipulates only the media feature of interest without concurrently manipulating other media features can be very difficult. However, care in manipulations is crucial because it is possible to unwittingly incorporate a confound into the study. Let's suppose that in the study mentioned above, Grabe and Samson had the female anchor read five news stories about the economy in the unsexualized condition and five news stories about entertainment celebrities in the sexualized condition (of course, they did not do this). In this case, a confound would be that the topics of the stories covaried along with the anchor grooming. Any difference found in a dependent variable (e.g., perceived professionalism) could be due to the story content and not the image of the anchor. The reason why we create variance in the independent variable is twofold. First, variation in the independent variable is a necessary (but not sufficient) condition to detect covariation with the dependent variable. Second, the manipulation helps to set up the time order of events where the independent variable occurred prior to the measurement of the dependent variable.

Research Questions That Can Be Addressed by Controlled Experiments

A good research question that can be addressed by a controlled experiment must ask about the causal relationships between at least two variables. These variables must be observable by either manipulation (independent variable) or measurement (either independent variable or dependent variable). A good way to begin to frame a simple

research question is to ask, “What is the relationship between A and B?” where A and B are your two variables of interest (for argument’s sake, let’s say that A is your independent variable and B is your dependent variable). The benefit of beginning with this type of question is that it makes you think of your study in terms of your variables rather than in terms of a topic. Another benefit of this question format is that it requires you to think about the kind of relationship you think might exist between your independent and dependent variables. Does a change in A cause a change in B? If so, does variation in A *increase* B or *decrease* B? It is difficult for a researcher (whether novice or expert) to begin designing an experiment without first asking the research question in this or in a similar form. In a classic study, Janis and Feshbach (1953) asked if increases in levels of fear in a persuasive message (the independent variable; theirs had three levels) affect message effectiveness. Message effectiveness was represented by a variety of dependent variables that measured beliefs, attitudes, and behaviors.

Designing an Experiment

Let’s suppose that you have a research question about the causal relationship between two variables. As you think about the steps needed to insure that any change in the dependent variable is due solely to changes in the independent variable, you soon realize that there are dozens of important decisions to make. While these decisions are addressable when handled with sufficient knowledge, each involves making choices that often do not have easy answers. The key is to make those choices having understood the benefits and costs of each decision. Keep in mind that any “cost” that adversely affects the internal validity of an experiment is likely to be a major obstacle to learning much about the causal relationships you are seeking to test.

The literature refers to several different kinds of experiments. The seminal resource on experimental design is Campbell and Stanley’s (1963) *Experimental and Quasi-Experimental Designs for Research*. Campbell and Stanley identify six designs. Three are described as “pre-experimental designs” and the other three as “true experimental designs.”

The pre-experimental designs include one-shot case study, one-group pretest–post-test, and a static-group comparison. The main problem with the first two designs, and why Campbell and Stanley refer to them as “pre-experimental” designs, is that they include no comparison groups. Recall (above) that one of the goals of the experimenter is to identify covariation between independent and dependent variables. In both the one-shot case study and the one-group pretest–post-test designs, what might be considered the independent variable is in reality a constant. That is, the independent variable is not a variable at all because it doesn’t vary.

The static-group comparison does have a comparison group, but the main problem with that design is that there are no formal means to insure that the groups are equivalent beyond the manipulation. Thus, this design has possible confounds built

into it and the causal influences of the independent variable on the dependent variable cannot be established with confidence. Because none of these designs can establish a cause and effect relationship, Campbell and Stanley call them “pre-experimental” designs. Others have referred to them as “quasi-experimental” designs.

True Experimental Designs

Campbell and Stanley describe three “true” experimental designs: pretest–post-test control group design, post-test-only control group design, and the Solomon four-group design. The three designs are adequately explained elsewhere (e.g., Bradley, 2011; Campbell & Stanley, 1963; Grabe & Westley, 2003). The key features of these designs are the inclusion of (1) experimental conditions, (2) comparison groups, and (3) random assignment to conditions. Experimental conditions represent the levels of the independent variables and help to determine if there are differences in the dependent variables that are due to your conditions. The comparison group, sometimes called a control group, is important because it controls many threats to validity (e.g., history, testing, maturation) that could yield alternative explanations. Random assignment to condition also controls for alternative explanations due to individual differences of your participants.

Factorial Studies

Perhaps the most common type of experimental design in media studies research includes at least two independent variables. When these variables are crossed (meaning that each level of each independent variable also occurs at another level of another independent variable) they are called factorial designs. In factorial designs, independent variables are called factors. Factors generally refer to manipulated independent variables, such as when one group of participants sees one kind of message and another group sees another kind of message. Factorial designs are expressed in the number of factors (i.e., independent variables) they have, and the number of levels of each factor. For example, a 2×2 factorial study has two independent variables, each with two levels. A 2×3 factorial study also has two independent variables, where the first independent variable has two levels and the second independent variable has three levels. By definition, each factor must have at least two levels since independent variables must vary (that’s what makes them *variables*) even if they are nominal variables (e.g., present/not present; high/low; one medium versus another medium).

Factorial studies have several advantages compared to single independent variable designs. They permit the simultaneous analysis of two or more independent variables. This design can be more efficient than a study that has only one independent variable because it can cost less in terms of the number of participants needed

and the amount of time it takes to run the study. But just as importantly, factorial designs permit the researcher to examine interactions – when the influence of an independent variable on a dependent variable may depend in part on the level of another independent variable in the design.

The simplest factorial design is a 2×2 design. An example of a 2×2 factorial design would be an experiment that asks the question “What is the impact of fear appeals and channel on message compliance?” In this case, there are two independent variables. The first is fear appeal, which can be operationalized as a message having a fear (threat) component and one that does not. The second independent variable could be operationalized as the medium format (e.g., radio/television). A graphical representation of the 2×2 design is shown in Figure 10.1.

Notice that this design shows four boxes. Each box represents something about the condition in which it appears: Box A represents the condition of a fear message on radio; Box B represents the condition of a fear message on television; Box C represents the no fear message on radio; and Box D represents the condition of a no fear message on television. You can put different types of information in each of these boxes, such as the stimuli for each condition, the order of the stimuli, the means and standard deviations on one of the dependent variables, and so on. A graphic like this helps to organize your study.

Suppose you wanted to add a third condition to the medium variable that represented a message presented on the Internet. You could envision a 2×3 factorial design (see Figure 10.2), where the first independent variable is still the fear appeal (fear/no fear), but the second independent variable (medium) now has three levels (radio/television/Internet). A fully crossed design would have six conditions. As a general rule, experimental designs that have more than three factors can be problem-

		Medium	
		Radio	TV
Message type	Fear	A	B
	No Fear	C	D

Figure 10.1 A 2×2 factorial design

		Medium		
		Radio	TV	Internet
Message type	Fear	A	B	C
	No Fear	D	E	F

Figure 10.2 A 2×3 factorial design

atic, even if each factor has only two levels (Smith, Levine, Lachlan, & Fediuk, 2002) as they become harder to interpret.

Confounds

When designing an experiment, there are additional important issues to consider. Several have to do with eliminating confounds. A confound is a source of variation that is inextricably tied to one of the independent variables. A confound makes it impossible to determine what is having the observed effect on any of the dependent variables. Eliminating confounds can be accomplished, in part, by paying close attention to treatment variance among conditions, that is, to the process of operationalizing independent variables.

Often, manipulated independent variables in media studies experiments have to do with the form and/or content properties of messages. The fundamental consideration in thinking about message manipulations is to design them in such a way as to eliminate confounds. Sometimes that requires that the message be controlled to such a point that it may not represent actual media messages very well. Although external validity of messages used in experiments is important, the internal validity of message manipulations is even more crucial because, without the confidence that confounds have been avoided, there is little reason to conduct an experiment. We have already discussed how having the female anchor read five economic stories in the “sexualized” condition and five celebrity entertainment stories in the “unsexualized” condition would have introduced a confound in Grabe and Samson’s (2011) study. Instead, the authors kept other message properties constant. They knew that simultaneously altering stories would have resulted in what some academics refer to as a “fatal flaw.”

Creating Treatment and Message Variance

The most common way of creating treatment variance in media studies controlled experiments is through message alteration, where the researcher either alters existing messages to create different versions (each of which represents a level of an independent variable), or first creates the messages, and then different versions of each. The point of message alteration is to change only the attribute of a message that represents a level of an independent variable while keeping the rest of the message constant. In their study on the effect of compelling negative images in TV news stories on memory for story content, Newhagen and Reeves (1992) created two versions of news stories to represent their news story independent variable – compelling negative images in news stories (absent/present). First, they collected stories about disasters (e.g., hurricane, riots, accidents, etc.). Then they created two versions. In

one condition, they inserted compelling negative video footage in the middle of the story. In the other, the stories had no compelling negative video. Based on this manipulation, the researchers were able to see how the presence of the negative video impacted memory for the story.

Another issue is deciding how many messages should represent a level of a treatment. Is one enough? This is not an easy question to answer, especially since accomplished researchers vary on their positions. Detailed discussions of the benefits of including message variance in design are discussed elsewhere (Jackson, O’Keefe, Jacobs, & Brashers, 1989; Reeves & Geiger, 1994; Slater, 1991; Thorson et al., 2012). Thorson et al. explain that two kinds of variance are important in experiments – treatment variance and message variance – and they argue that both are important in media studies experiments. Treatment variance refers to how the levels of each independent variable vary within the message. Often, experimenters focus primarily on treatment variance and not enough on message variance – employing multiple messages per treatment level.

Suppose you were interested in how news sources affect the perceived credibility of news stories. You might choose or write a news story and create two versions, one in which the primary source is a government official and another in which the primary source is a private citizen. In this case, you have created variance between your two treatment levels (government source versus private citizen) and held all other message features the same. This is an example of creating treatment variance through message alteration, which is common in media studies. However, this design, sometimes called a “single message design” is problematic because it ignores message variance (Thorson et al., 2012). That is, any effect you might obtain with this message alteration may be dependent in part on other features of the message that were held constant. Suppose your news story was about the effort of the local government to levy an additional sales tax. It is possible that the source effect you found may only occur in stories that focus on taxes, on economic issues, on financial concerns, or on the gender of the particular sources you used, and so on. It is impossible to determine if the observed effect is unique to that story. One way to reduce this problem is to create message variance. Employing multiple messages per treatment level strengthens the ability to generalize to message categories.

In addition to message alteration, one can create treatment variance by employing a sample of messages so each level of an independent variable is represented by several messages. When selecting a sample of messages to represent each treatment level, the researcher would ideally sample from a knowable message population that contains all of the messages that represent a particular treatment. Rarely, however, do we have access to such a population of messages. Often, the best we can do is find multiple messages that represent one treatment, where the variance within treatment would ideally be less than the variance between treatments. Given that messages vary on a host of features other than the ones of interest, many of which we cannot know, Thorson et al. (2012) and others (e.g., Reeves & Geiger, 1994) suggest that the best strategy is to include as many messages per treatment

level that participants can reasonably be expected to attend to without fatigue or boredom. The more messages naturally vary within a treatment, the larger the number of messages per treatment is needed. This strategy creates both treatment and message variance.

Lee and Lang (2009) provide such an example. They tested the effects of five discrete emotional public service announcements (PSAs) – fear, sadness, joy, anger, neutral – on several cognitive and emotional dependent variables, including self-report and psychophysiological measures. Based on pretest ratings, Lee and Lang selected 30 PSAs to represent the five-level discrete emotion independent variable. Six different messages represented one of the five conditions. Note that this message repetition procedure created both treatment and message variance. Clearly, messages within a single treatment varied widely, but within-treatment message variance was treated as random error in tests across treatments. The significant findings of their study occurred despite this within-treatment message variance. This approach is becoming more common in media studies, especially as continuous response and psychophysiological measures spread across research laboratories in journalism, communication, and media studies programs.

Another option for creating both treatment and message variance is to employ both message alteration and message repetition strategies. An example of such a study is a 3×2 experiment in which Miller (2006) manipulated story type (three levels: live, breaking, traditional) and emotional message content (two levels: threat, negative graphic images). She created treatment variance for story type with message alteration by having an anchor verbally refer to a story as “live” or as “breaking,” or by including no verbal designation for the “traditional” story. To create treatment variance for emotional content, three stories were chosen to represent the threat condition and three different stories were chosen to represent the negative graphic image condition. Miller used a fractional design, such that each participant saw six stories that represented the six levels of the two independent variables (traditional–threat, traditional–graphic image, live–threat, live–graphic image, breaking–threat, breaking–graphic image, presented in random orders). No participant saw two versions of the same story. By including a message repetition factor for the emotional content treatment, Miller was better able to generalize her results to other similar emotional news stories than if she had relied on only one story per condition. Although message repetitions may require more work on the part of the researcher, their inclusion in an experimental research design greatly strengthens what can be learned from a study.

Operationalizing Independent Variables

There have been discussions in the literature on how to characterize the structure of media stimuli, as summarized in O’Keefe (2003), Tao and Bucy (2007), and Thorson

et al. (2012). Many scholars define media stimuli in “industry units” (e.g., commercials, news stories). There are good reasons for such a choice. Much of our research interests involve how people respond to news, ads, programs, stories, and other such journalism and advertising products. Other scholars suggest it is often more useful to describe media messages in terms of variables more closely related to how messages are psychologically processed (Reeves, 1989). This approach emphasizes form and content message attributes such as visual complexity, brightness, contrast, movement of objects on the screen, story length, tone, frame, arousing content, and so on. This distinction becomes increasingly important if research questions focus on the impact of specific formal (e.g., pacing, type size, color, movement) or content features (e.g., emotional content, bias, sources, attacks, acclaims).

One common mistake media studies students new to experimental research make is confounding message attributes with their intended effects. The classic example is research on “fear appeals.” Understanding how fear appeals work to change individuals’ knowledge, attitudes, and behaviors about health threats has been examined with experimental research since the mid-1950s. It is tempting to define a fear appeal message in terms of the effect it has on a participant (i.e., a message that scares someone). Although frightening an audience member may be the goal of a fear appeal, that definition does nothing to tell us how to create one. A better approach to operationalizing a fear appeal is to decide which message features constitute such an appeal. Perhaps the most common definition of a fear appeal is as message content that contains a threat to the well-being of target individuals (Dillard, 1994). Note that in practice, “fear appeals are executed by writing copy in a way that directly associates the targeted behavior (e.g., tobacco use) with a threat (e.g., disease, death)” (Leshner, Bolls, & Wise, 2011, p. 79). Note that the content described here is independent of how an individual feels upon exposure.

Sundar (2004) provides another example with the concept of interactivity. He points out that if interactivity is conceptualized as a feature of the physical stimulus, then it is a mistake to operationalize it in terms of people’s perception of interactivity. Instead, it is necessary to develop a theory of what it is about a stimulus that makes it interactive (e.g., features like functionality, user accommodations, organization, control, choice, and contingencies). These features are physical, not psychologically perceived independent variables.

Operationalizing Dependent Variables

Dependent variables in media studies experiments often share properties with those measured in survey research. Most often, dependent variables tend to be continuous measures, meaning that they are measured on ordinal interval or ratio levels. These include Likert scales, semantic differential scales, and magnitude response scales (e.g., seven-point scales anchored by “not at all” and “a lot,” or “never” and “always”). Such

scales have been used to measure attitudes, opinions, and behaviors. Researchers can compute the means and standard deviations across conditions to see if being in a condition affects those responses. Knowledge and/or memory can be measured by factual tests (e.g., series of multiple choice items summed to create a “knowledge” score for each participant). Other types of self-report measures include cued and free recall, thought listing, thinking aloud, and so on. Self-report dependent variables can have problems associated with them, such as social desirability (Crowne & Marlowe, 1960), demand characteristics (Orne, 1969), and satisficing (e.g., Krosnick, Narayan, & Smith, 1996). As more media studies research investigates how individuals process media messages, researchers are adopting dependent variables used in psychology and other fields. Many of these are implicit measures, meaning that they are less susceptible than self-report variables to the threats to validity mentioned above. These can include secondary task reaction time (STRT), which can include response latency (how long it takes the participant to respond) (Geiger & Newhagen, 1993), speeded recognition tasks, and psychophysiological measures (e.g., heart rate, skin conductance, facial electromyography, startle) (Potter & Bolls, 2011). These measures can require sophisticated equipment and software as well as considerable training and theoretical understanding. Even so, laboratories that can accommodate these types of measures are becoming more common in journalism, communication, and mass communication programs. There are currently upward of two dozens psychophysiological research laboratories in the United States supervised by mass communication researchers, and several more outside the United States.

Between or Within Subjects?

A major decision that needs to be made in any experiment in media studies is deciding what participants will see, hear, or read. Specifically, would each participant see stimuli that represent only one level of an independent variable (between subjects), all levels of all independent variables (within subjects), or some levels of some independent variables (mixed)? The most common strategy in media studies is the between-subjects design, where participants are randomly assigned to only one level of an independent variable. The within-subjects design is a repeated-measures design where participants see all levels of all independent variables. The third option is having some independent variables run between subjects and some independent variables run within subjects.

Between-Subjects Designs

In between-subjects designs each participant is randomly assigned to a condition. Comparisons can be made across conditions on the values of each dependent

variable. The advantages of between-subjects designs are that procedures are generally easier and you don't have to worry about participants figuring out your manipulations. Also, treatment orders are not considerations in between-subjects designs. Since each group is exposed to different treatment levels, the mean scores (systematic variance) on each dependent variable are compared relative to their within-group variation (error variance).

An example of a between-subjects design is the previously mentioned fear appeal study by Janis and Feshbach (1953). The researchers developed three versions of a 15-minute illustrated talk about the causes of tooth decay and oral hygiene recommendations. Included in the talk were 20 slides illustrating points being made by the speaker. All three versions presented essentially the same content, but they varied in the amount of fear-arousing material presented: strong fear, moderate fear, or minimal fear. Participants were high school students who were assigned to either one of the three fear conditions or to a fourth group, which acted as a control group, who saw a presentation on a different topic. The design permits the comparison of scores on dependent variables across the four groups (or the three fear groups on measures that could only be asked of participants who saw one of the fear messages). Since participants were not exposed to other conditions, Janis and Feshbach did not have to worry about threats to validity that may occur when participants are exposed to multiple levels of an independent variable, such as sensitization and carry-over effects.

Within-Subjects Designs

Within-subjects designs are less common in media studies, although the frequency with which they appear in media-related journals is increasing, in part due to the growth of media psychology research. In within-subjects designs, each participant receives all of the manipulations, regardless of how many independent variables and levels of each there are. The main advantage of within-subjects designs is that each participant acts as his or her own control, meaning that the amount of error variance per condition is greatly reduced. The consequence of reduced error variance is that the same size effect can be detected with many fewer participants than in a between-subjects design. This means that, all things being equal (the same number of conditions), within-subjects designs can be considerably less expensive to conduct in terms of both time (experimenter and participant) and money. However, within-subjects designs can have a major drawback. Since every participant experiences all levels of all independent variables, it is possible (even likely in many situations) that they could be sensitized to the manipulations, which could in turn impact their responses. Further, within-subjects designs are susceptible to carry-over effects, which means that the induction of one treatment impacts the induction of the next. It is very difficult to eliminate carry-over effects, if they occur, in within-subjects designs. The most common strategy to deal with possible carry-over effects is to randomize

the presentation order of stimuli to participants. Although carry-over effects are not eliminated, this approach treats the impact of presentation order as error.

Sample Sizes

An important decision to be made is the size of the sample needed to conduct an experiment. This consideration is primarily informed by the size of the effect to be detected, the number of factors and levels of each, whether factors are run within subjects or between subjects, the type of statistical analyses to be conducted (e.g., ANOVA (analysis of variance), regression), and the statistical criterion for rejecting the null hypothesis.

In order to determine sample size, you will need to have an *a priori* idea of how large an effect you wish to detect. You can estimate effect size by reviewing literature and seeing what effect sizes others have found in studies that used variables similar to yours. If insufficient information from prior literature exists, then you may need to estimate effect size either by reasoning from theory or by using rules of thumb. Cohen (1988, 1992) categorizes effects as “small,” “medium,” and “large.” Clearly, the choice of such a crude classification will depend on the specifics of the research. For example, we might expect to find a “medium” sized effect when doing a study on priming, but a “small” sized effect if measuring heart rate. Absent any convincing evidence for *a priori* effect size estimates, most researchers opt for expecting a “medium” sized effect. Once you have chosen the effect size you wish to detect, you will need to determine which independent variables you wish to run between subjects and which you wish to run within subjects. For within-subjects independent variables, you may need to estimate the correlation among the repeated measures. The statistical tests you wish to run to test your hypotheses will be determined by your design. Finally, your criterion for rejecting the null, also called type I error, is set by convention at $\alpha = .05$ (admittedly this level is arbitrary).

There are several power analysis software packages you can use to compute *a priori* effect sizes, some of which are free (e.g., Faul, Erdfelder, Land, & Buchner, 2007). There are also rules of thumb that can be used (e.g., VanVoorhis & Morgan, 2007), although this approach can be less precise than a power analysis program, tables, or computation. Cohen (1988) for example, provides power tables for multiple statistical tests and research designs.

Sample Composition

There has been considerable discussion in journals of whether it is necessary to randomly sample experimental participants from a targeted population (Abelman,

1996; Basil, 1996; Basil, Brown, & Bocarnea, 2002; Courtright, 1996; Lang, 1996; Potter, Cooper, & Dupagne, 1993, 1995; Sparks, 1995a, 1995b). This issue feeds into a larger theoretical one, which is, to what do we wish to generalize (Shapiro, 2002)?

When researchers randomly sample from a population, they can infer from findings in the sample to the particular population from which the sample was drawn. For example, if a researcher obtains a random sample of people in a county to study support for a local ballot initiative, the percentage of people who respond positively can be used to estimate the actual support in the county's population, within the sample's sampling error. Random sampling enables statistical generalization from sample attributes to population attributes.

Samples for experiments in media studies, however, rarely involve random samples. In fact, one does not have to read many reports of experiments in mass communication to recognize the fact that nearly none employ samples randomly selected from populations. Instead, experimental researchers typically acquire convenience samples (e.g., college students enrolled in large communication classes, or adults who agree to participate in an experiment for a chance to win a retail store gift card). These individuals are then randomly assigned to the conditions in the experiment. Because there is no random sampling of participants, inferences cannot be applied to the likelihood that values found in the experimental sample are representative of values that would be found in the population as a whole. Instead, logical inferences are made about the multivariate relationships among the variables in the experiment (Basil, 1996; Basil et al., 2002). Lang (1996) explains that the "population" in experiments is all the possible samples one could randomly draw from the group of individuals in the experiment.

The strength of those logical inferences depends on how well the experimenter can make the argument for them, which should be based on a combination of theoretical and conceptual considerations. For example, suppose a study examined the relationship between exposure to emotional media and psychophysiological processes that are unlikely to be affected by demographics or other individual difference variables. Then generalizing to "human processing" could be argued since those processes are expected to be similar across samples with different characteristics. On the other hand, if an experiment involves variables clearly related to demographics or individual differences, then generalization beyond people who do not share those characteristics would be unconvincing. Often the generalizability of experimental findings is also supported by replication of the experiment across different samples of both people and messages and across different contexts. A good example of a finding that seems to be robust regardless of when or where it is tested is the third-person effect.

In his cogent discussion about the differences between social and surface realism, Shapiro (2002) argues that generalizability is inextricably linked to the theoretical principles that underlie our controlled observations (in the case of experiments). Thus, the focus on what we can learn about the processes involved in much media studies research should be more on the theoretical relationships among variables and

less on surface similarities, such as random sampling or the operationalizations of variables. Basil et al. (2002) showed that multivariate relationships can be stable across samples even when the samples differ greatly on demographic variables and the data collection method. Basil and his colleagues conducted a study of celebrity effects around the time of the death of Diana, princess of Wales, with three different samples: a random telephone sample drawn from seven states, a nonrandom sample of college students in three states, and a nonrandom web-based survey sample. The samples varied widely in terms of age, gender, and media use, yet Basil and his colleagues found a remarkably consistent relationship across the different samples between respondents' identification with Diana and their media use. Thorson et al. (2012) recommend that sample characteristics and selection methods should be reported so the reader can evaluate claims of generalizability.

Manipulation Checks

Manipulation checks are traditionally included in media studies research, especially in studies in which a message manipulation represents levels of an independent variable. For example, some fear appeal researchers will manipulate the level of threat in a message, then measure participants' perceived threat or fear arousal in order to be certain that the message manipulation performed the way in which it was intended. However, this approach has come under considerable criticism (e.g., O'Keefe, 2003; Tao & Bucy, 2007; Thorson et al., 2012). The criticism is based on three arguments: (1) message manipulations are independently verifiable; (2) message manipulations are conflated with effects; and (3) mistreating measures as manipulation checks when they could be treated as mediating psychological states.

The first argument can be illustrated with a study reported by Lang, Schwartz, Chung, and Lee (2004). They defined pacing of videos, which they hypothesized would impact message processing, as the number of scene changes per unit of time with public service announcements. That is, PSAs with few scene changes represented "slow" pacing and PSAs with many scene changes represented "fast" pacing (they included a third condition, where a moderate number of scene changes represented "medium" pacing). The average number of scene changes per condition is verifiable – either pacing (or rate of scene changes) varied across the three conditions or they didn't. Asking participants their perception of pacing as a check on actual pacing is unnecessary.

The second argument can be demonstrated by the fear appeal example, in which perceived threat (important in a number of fear appeal processing models) and/or fear arousal are measured and treated as checks that the message manipulation has worked as expected. In research where the theoretical interest is on the message attributes that increase fear, such a manipulation check is not measuring the

message feature; rather it is measuring the effect the manipulation has. In other words, this approach defines the media content by its presumed effects and not by the particular message features of theoretical interest. O’Keefe (2003) specifically argues that conceptualizing media content according to concrete message properties that can be manipulated during message production provides more theoretical and practical value for media processes and effects research than defining it according to how it impacts participants.

The third argument involves not so much measurement but how those measures are handled during data analyses. O’Keefe (2003) argues, for example, that if messages are manipulated based on the intensity of the health threat (e.g., the threat can reduce the ability to climb stairs versus the threat can kill you) and perceived threat is measured, then perceived threat could be thought of as a mediating psychological state, and therefore should be included as a mediator in subsequent analyses. Too often, researchers will present perceived threat as a manipulation check rather than include it analytically in a mediation model. Such treatment would add considerable value to our theoretical models.

To sum up, O’Keefe argues that manipulation checks, as such, are unnecessary:

From my vantage point, a researcher who reports a message manipulation check has probably made one of two mistakes – either the mistake of defining a message variable in terms of effects rather than in terms of intrinsic properties or the mistake of confusing the assessment of a potential mediating state with the description of message properties. (2003, p. 268)

Summary

The controlled experiment is a valuable, if underutilized, research method in media studies. It is the best way to show a causal relationship between variables because it can set up a temporal order of events (independent variables occur prior to the measurement of dependent variables) and eliminate alternative explanations by eliminating confounds. The key aspects of a controlled experiment include manipulations of independent variables, random assignment to conditions, and controlling all other variables. When variations in message properties represent different levels of independent variables, manipulations can be accomplished through message alteration or message sampling. Message sampling can also increase generalizability of the findings to other similar messages. Many experiments in media studies are factorial designs, where more than one independent variable is systematically varied. These designs allow the examination of interactions in addition to main effects. Samples based on college students should not be discounted out of hand. There are cogent arguments against manipulation checks, although measures of perceived message effects can be theoretically important as mediating variables.

Between-Subjects Experimental Design and Analysis

Kim Bissell

ABSTRACT

Media effects and media studies researchers have recently been forced to determine the most effective way to measure the media's influence on individuals or groups. While thousands of media effects studies exist, the study design employed has varied. Between-subjects experimental design is increasingly becoming one of the most statistically valid ways to determine the effect of stimuli on a target population because every participant is only exposed to the treatment or stimulus once. This design allows researchers to make comparisons between groups based on each group's response to the stimulus material or treatment. This chapter provides a case study of a between-subjects experimental design using a sample of 601 children who participated in an experiment designed to measure weight stigmatization and bias following exposure to one image of an overweight or thin individual. Finally, the chapter discusses the advances and disadvantages to the design in this case and proposes directions for future research.

An experiment is a mode of observation that enables researchers to probe causal relationships. Many experiments in social research are conducted under the controlled conditions of a laboratory, but experimenters can also take advantage of natural occurrences to study the effects of events in the social world.

Experimental design is one of several quantitative research methods used in mass communication to study the relationship between mediated content and subjects' knowledge, beliefs, perceptions, and behavior. Wimmer and Dominick (2006) argue that experimental design is the oldest methodological approach used in mass communication research and certainly the most appropriate method for studying and understanding the effect of media content on audiences; however, the method itself is used relatively infrequently in mass media research (Wimmer & Dominick, 2006). Experiments have been used in media research to examine the following types of phenomena, along with many other topics: the effects of exposure to violent media on aggressive thoughts and behavior; the effects of exposure to highly sexualized content on attitudes about women as objects rather than subjects; the effects of negative political attack ads on voter attitudes toward candidates; the effects of health messages in advertisements on viewers' dieting behavior; the effects of video game playing on cognitive overload and secondary task behavior.

The beauty of an experiment is the ability to demonstrate causality; however, when examining social artifacts and human behavior, researchers' ability to state with certainty that variable X caused a change in variable Y or that the independent variable (IV) is what caused a change in the dependent variable (DV) is low.

The following chapter explores one form of experimental design – between-subjects experiments – and uses two projects as a case study of the advantages and disadvantages to this specific design. Through a discussion of the two experiments, the study design employed, the stimulus material used, and the sample selected, the strengths and weakness of this form of experiments will be examined.

In designing an experiment to determine the effect an independent variable has on some dependent variable, the researcher is faced with the choice of manipulating the stimulus (usually the independent variable) between or within subjects (Erlebacher, 1977). Some researchers have tested the two designs to see if similar results can be found. The ultimate question in these earlier studies of the methodological soundness of each approach was whether the design type interacted with the independent variable (Schrier, 1958). Erlebacher (1977), also known for the development of a statistical test often used in experiments, the ANOVA (analysis of variance), addressed the use of a between- and within-subjects design and reported the following: "The design type (between or within-subjects) is treated as an explicit independent variable in a factorially designed experiment. The outcome of the experiments is that there is an interaction between the design type and the substantive independent variable" (p. 212). More simply, Erlebacher is suggesting that there are differences between the two designs, and for researchers, it is important to know which design would be most appropriate given the purported interaction between the design type and the independent variable. Most experiments in personality or social psychology tend to be conducted using a between-subjects design, and because so many of the studies within mass communication are derivatives or have origins within social psychology, experiments in mass communication and media studies have often followed suit.

Both within-subjects and between-subjects designs have their relative strengths and weaknesses. A between-subjects design allows for comparisons across at least two or more groups, whereby subjects randomly assigned into one or more experimental groups will be observed on the outcome variable or dependent variable following exposure to stimulus material. For example, if a researcher were interested in examining the physiological effects of exposure to scary content presented in 2-D and 3-D formats, the researcher could design a between-subjects experiment whereby participants assigned to one experimental group would view the scary content in 3-D format while physiological data was recorded (heart rate, skin conductance, EEG data), and participants assigned to another experimental group would view the same content in 2-D. A researcher in this case would most likely also include a control group who would not view any scary content at all so that baseline measures of the physiological data could be compared across groups. If statistical results indicated that participants in the 3-D group had a higher heart rate, increased skin conductance, and more EEG activity than participants in the 2-D or control group, the researchers could effectively assert that exposure to 3-D content caused an increase in physiological activity.

A within-subjects design is thought to be stronger in internal validity because the design is not dependent upon random assignment. In short, internal validity is the degree to which the study reflects or measures what it says it is measuring. In experiments, internal validity insures the design closely follows the principle of cause and effect. The statistical “power” from a within-subjects design – that is, the likelihood that a study will detect an effect when there is an effect to be detected – is also often greater than it is for between-subjects designs. Finally, the design, by its very nature, is more naturally aligned with what we think about when we consider experiments – a study designed to examine how particular stimuli might be related to a specific outcome in a subject (Charness, Gneezy, & Kuhn, 2012). While the benefits for this type of experimental design are great, the design does not easily allow for comparisons of multiple stimuli (as easily or without confounds), and external validity – the ability to make generalizations to a broader population – is not as high.

The choice of one type of design over another will be dependent upon a number of factors: (1) what research question or hypothesis is being tested; (2) what the concerns are over potentially spurious effects, whereby subjects act in accord with the way that satisfies the researcher’s expectations; and (3) what the need is for statistical power (Charness et al., 2012). In any kind of empirical research, there are four key components that influence the degree to which conclusions can be reached from a statistical test. These factors are especially important in experimental design as all four are essential in properly designing a study in a way that will yield statistical significance. Statistical inference, or the ability to draw conclusions based on the statistical tests used, is dependent upon the sample size, the effect size, the significance level, and the statistical power (discussed above). If the sample size is small overall or within a specific cell in a between-subjects design, the likelihood of statistical significance being found decreases. Effect size is a numerical way of expressing

the strength of a reported relationship. The significance level refers to criterion level used to reject the null hypothesis. All four factors are crucial in a researcher's ability to reject the null hypothesis and state that X caused Y.

What follows is a description of two between-subjects experimental design studies conducted over the last few years. These studies will be used to discuss the methodological strengths and weaknesses of the between-subjects approach and to highlight the ways media studies researchers can correct or overcome some of the limitations of this specific design.

Case Study: An Examination of Anti-Fat Bias in Grade School Children

Two separate studies were conducted over the course of three years to better understand the factors influencing the development of bias against overweight and obese individuals. However, the samples were different in each study, and the measures were modified based on the age of the participants. One of the studies was conducted with children and one with adults. Procedures were similar across the two studies, and the independent and dependent measures varied only in word usage and sentence length. These decisions were based on the age and literacy rate of each sample's participants. The objective of each of the studies was to identify correlates or precursors to weight bias. Thus, in each of the studies, a between-subjects experiment was conducted. With this design, I was able to prime participants with an image of an overweight or a thin subject and then use cognitive and attitudinal measures to assess participants' weight bias. The objective of both studies was to identify the factors – individual, social, media, or ideological – that might be the strongest predictors of bias in each of the two separate samples.

The first experiment, focusing on children, was designed to be a 2×5 between-subjects experiment. This study used four experimental groups and one control group. The first factor of the design was participant gender, and the second factor was the experimental group in which the subject was randomly assigned. Gender was included as a factor in the study because previous literature has indicated that girls have a greater bias than boys against other overweight girls. Thus, while one study objective was to determine the correlates or precursors of weight bias in children, another objective was to understand how the participants' gender interacted with the stimulus material. The 2×5 experiment yielded 10 conditions whereby boys and girls were randomly assigned to one of the five groups and then participant gender was used as a factor in statistical analysis.

In both studies, participants completed an online instrument and addressed items related to self-perception, peer and family influence, household dieting behavior, eating and exercise behavior, eating and exercise attitudes, and media exposure. These variables were largely used as control variables or as co-variates (a variable

that may possibly also predict the outcome under investigation) with the independent variables (experimental group and gender). Participants also completed a modified version of the implicit association test (IAT), designed to measure attitudes related to weight. The IAT was developed by social psychologists Greenwald, McGhee, and Schwartz in 1998, and was designed to detect the strength of an individual's automatic association between mental representations of objects or people in memory. The IAT has been used in many experiments to gauge adults' implicit bias against gender, ethnicity, sexual orientation, and disability. While the IAT has been criticized by other social psychologists, it is still the most widely used measure of implicit bias against different personality and physical characteristics.

Children participating in the first study viewed and completed the instrument at school during computer lab time. For this study, child participants were randomly assigned into one of the five groups in the hope that there would be no differences across groups. The second study was an online experiment with adults, whereby participants were also assigned to one of the five groups. Using this randomized sorting method would guarantee that each of the five groups had roughly the same number of participants or a similar cell size. In the adult study, all items were viewed and completed online without any interaction with the researcher.

Each study included four experimental groups and one control group. In order to facilitate responses to photographs of overweight and thin children/adults – child participants viewed images of children and adult participants viewed images of adults – participants were randomly assigned one of the following groups: exposure to an image of an overweight female; exposure to an image of the same female who was thinner; exposure to an image of an overweight male; exposure to an image of the same male who was thinner; and no image exposure (control group). Thus participants were exposed to an image of an overweight man/boy or woman/girl in two of the four experimental groups. The purpose was to see if exposure to an overweight subject might trigger greater amounts of bias against overweight. By design, both male and female participants would be randomly assigned to one of the five groups, but because participant gender was a factor, a total of 10 groups were created.

Identification of the subjects/individuals used as stimuli in the two experiments was based on a pilot test of 16 images of thin and overweight males and females using a sample of other children and adults. The images selected for use in both projects were “before” pictures of males and females who had participated in weight-loss camps or weight-loss treatment programs. For the “overweight” treatment groups (one male, one female), full-body images were selected. Both photographs showed the subjects smiling so that no negative effect would be associated with facial expression. The subjects were photographed in bathing suits for both the “before” and the “after” images so that confounding factors could be eliminated. For the “thin” treatment groups, “after” images of the same male and female were used, and the images were enhanced in Photoshop so that the “thin” treatment group was exposed to an image of a clearly thin person. The fifth group did not view an image, and this

group served as the control group. Experimental group was a key independent variable for both studies, as the subject in the stimulus photograph was selected in order to prime thoughts and attitudes about weight.

Since the outcome under investigation in both studies was anti-fat bias (AFB), two measures of AFB were used to try to better understand the correlates or precursors of weight bias. The dependent measures for both studies were similar: two measures of explicit bias. For the first measure, participants' attitudes about the subject viewed in the stimulus photograph were measured. Participants randomly assigned to one of the four treatment groups were asked seven questions related to the subject viewed in the photograph. Statements used in each experiment were items such as: "This girl/boy/woman/man looks like one of my friends"; "I think this girl/boy/woman/man is pretty/attractive"; "I think this girl/boy/woman/man is athletic"; and "I think this girl/boy/woman/man is popular." Using responses to the statements, an additive scale was created that measured explicit bias against the subjects viewed in the photographs. Reliability of this scale across the four studies ranged from a .68 to a .90, with the higher reliability coming in the two studies conducted with adults.

The second measure of explicit bias was a modification of Crandall's (1994) anti-fat attitudes scale, using the subscale of dislike. Items used in this study were a modification of the following statements: "I really do not like fat people much"; "I don't have many friends that are fat"; "I tend to think that people who are overweight are a little untrustworthy"; "Although some fat people are surely smart, in general, I think they tend not to be quite as bright as normal weight people"; "I have a hard time taking fat people too seriously"; "Fat people make me somewhat uncomfortable." This measure tapped into more general attitudinal bias against individuals who were overweight, as the items were not related specifically to the subject used in the stimulus. These types of statements gauge general bias against overweight versus a bias or dislike against a specific person who was viewed in the stimulus photograph. Some children may feel uncomfortable actively indicating a dislike for a specific person but may be more inclined to indicate a bias against more generic "fat people"; thus, the subscale of dislike provided the more general measure of anti-fat bias. It is acknowledged that viewing an overweight subject in the stimulus may have primed participants to think negatively about overweight individuals. However, the two scales measuring explicit anti-fat bias were separated by several filler questions and by the cognitive processing questions in each of the studies. Filler questions used in the study described included questions such as "What is your favorite subject in school?" "What is your favorite football team?" "Who is your favorite music artist?"

In a simple between-subjects experiment, it would be predicted that the stimulus would cause a change in participants' attitudes, perceptions, or beliefs about overweight individuals. Thus, the photographs for each experimental group were carefully selected so that increases or decreases in bias could be detected. This straightforward design would have allowed me to determine if variable X – the photograph of the overweight or thin subject – caused an increase in participant bias as

I could have compared mean scores across the experimental groups to see which group exhibited the greatest bias. With this design, the control group would be used as the baseline measure of the dependent variable (Y). While this design would have been appropriate, I felt I could not ignore other variables that might also be related to participant bias against overweight others. In the hard sciences, the stimulus will either cause an outcome or not. But, in the social sciences, an observable change in that outcome variable could be attributed to a multitude of factors. That is why I chose to include other measures in both studies. These measures allowed me to control for other possible predictors of anti-fat bias and to determine with greater confidence whether a trait characteristic shown in a mediated context (maybe repeatedly) would result in an effect on participants' beliefs about that trait.

Since the two studies examined the possible individual, social, media, and ideological influences on the development of bias in children and adults, the following variables were also used as either a control or independent variable: cognitive processing styles, demographics, media exposure, exposure to thin ideal media, self-perception as it relates to body image, household dieting behavior, peer influence, and sociocultural attitudes about appearance. A more detailed description of how these variables were measured is provided in the following section. For all variables listed above, measures were similar; however, in some instances, sentences were worded more simply so that child participants could understand the statements.

Study 1 Participants

The participants in Study 1 were 601 boys and girls aged between 7 and 13 (a more detailed description of the measures used and the study findings can be found in Bissell & Hays, 2011). About 21% of the sample were in 3rd grade, 19% in 4th grade, 30% in 5th grade, and 24% in 6th grade. Of the 601 participants, 45% were boys and 55% were girls, with ethnic representation closely matched to that of the counties where data was collected: 80% of the sample was White, 16% African American, and the remaining 4% Hispanic, Asian, or "other."

Study 1 Independent Variables

While many variables were used in the first study of the correlates of weight bias, the key factors under examination were related to individual variables, including gender and media exposure. Television viewing was measured using three self-report items. Children were asked to list the television shows they watched "yesterday before school," "yesterday after school but before dinner," and "yesterday after dinner but before bed." Children were instructed to type the names of television shows they had watched during those time frames in the previous day.

As a measure of self-perception, participants were asked several questions related to their fears about their own appearance. Items used in this experiment were modeled after Lundgren, Anderson, and Thompson's (2004) fear of negative appearance evaluation scale (FNAE). Several statements were rewritten to accommodate participants' reading level. Furthermore, reliability tests for the full scale were not sufficient, so items were eliminated from the scale for better reliability. Examples of items included statements such as "I care about what my friends think of the way I look," "I worry that other people will not like the way I look," and "When I meet new people, I wonder what they will think about the way I look."

Study 2 Participants

For Study 2, a design similar to Study 1 was used. In order to examine the relationship between possible predictors of implicit attitudes toward weight and obesity and the relationship of those implicit attitudes with more explicit attitudes of bias, a 2×5 design (gender $\times$ instrument version, between subjects) was used with adults in two states in the South. A total of 276 subjects ranging in age from 18 to 24 participated in the study. Approximately 67% of the sample was female and 33% male. A convenience sample was employed to recruit the 276 participants. Study 2 participants were recruited through participant pools at two universities, and students participated in the research project for extra credit.

Study 2 Independent Variables

All participants answered a series of questions related to media use, food intake, and involvement in physical activity and exercise. Participants then completed the implicit association test, designed to tap into implicit attitudes toward weight bias. Since participants completed this study online, a randomizing program was used to randomly sort each participant into one of the five groups (four experimental groups and one control group). Once assigned to one of five groups, participants in the experimental groups viewed one of four images (see stimulus description above) and then answered questions designed to measure explicit attitudes toward weight bias. Participants assigned to the control group did not view an image but answered similar questions related to weight bias.

After completing the first round of explicit measures of weight bias, all participants returned to the same section of the online instrument and completed other items related to self-discrepancy, exercise frequency, weight stigmatization, fear of negative appearance evaluations, and cognitive processing styles. Self-discrepancy items measured participants' perceived ideal self compared to their actual self, so participants were asked to circle a body shape that most closely represented their current or actual body shape and then (using a separate scale) were asked to circle

the body shape they felt most closely represented their ideal body. Exercise frequency measures included participants' involvement in sports for competition or recreation and/or general exercise and the number of minutes per day they spent participating in a physical activity. Weight stigmatization involved a single question that asked participants if they were afraid of becoming overweight. For Study 2, participants' self-reported exposure to media was used, and a body shape index for each of the television programs viewed was created, so that a thin-ideal viewing index could be created. The body shape index was calculated using an entirely different sample of participants who rated the body shape and size of the primary characters in the television shows participants indicated they had viewed. This enabled me to have a measure of participant exposure to thin-ideal media so that the role of media exposure in the development or reinforcement of bias against overweight could be better understood.

Summary of Results

For Study 1, a statistical test was conducted to see if there was any variation on the dependent variable across the experimental groups, so a between-subjects test was conducted using only five groups (four viewing a version of the stimuli and one viewing no image at all). Statistical tests indicated that participants (whether male or female) who viewed the image of the overweight girl were more likely to assess her unfavorably than participants who viewed the image of the thin girl. More specifically, exposure to the overweight girl in the stimulus photograph primed or triggered negative attitudes toward her. Participants exposed to the image of the overweight girl were less likely to indicate she was pretty, smart, or friendly, and were less likely to say they would be friends with her. The second measure of weight bias was a more general assessment of negative attitudes toward overweight and, again, participants randomly assigned to the "overweight" treatment groups in the experiment were more likely to exhibit negative attitudes toward overweight. For this study, the statistical test comparing the differences between groups indicated that, as predicted, exposure to an overweight subject in a photograph resulted in more weight bias using the specific and general measures of the dependent variable.

When statistical tests were conducted that examined all 10 groups (2×5), results indicated that female participants who viewed the image of the overweight female were the most critical or exhibited the greatest bias against overweight. Female participants who viewed the image of the overweight boy had the second highest bias scores followed by the male participants who viewed the image of the overweight girl. Thus, participant gender did play a role in increased bias as the mean scores for female participants viewing the image of the overweight female had the highest AFB scores of all.

When the other variables were examined statistically with experimental version, interesting patterns emerged, suggesting that in social science, factors outside of the

laboratory setting must be considered. For Study 1, media exposure and fear of negative appearance evaluations interacted with experimental group. More simply, the stimulus was found to cause a change in participant attitudes toward overweight others (for two of the four experimental groups – overweight male and female), but this effect varied when other independent variables such as thin-ideal media exposure and fear of negative appearance evaluations were included in the statistical test. The statistical test indicated that exposure to the stimulus photograph did prime or cue child participants to indicate a stronger bias against overweight individuals. However, for participants who indicated viewing higher amounts of thin-ideal television and for participants with a higher score on the FNAE scale, the bias against overweight was even greater. In short, two other variables that might also predict bias against overweight, coupled with exposure to an overweight subject, resulted in the greatest bias against overweight.

Study 2 was a between-subjects experiment with an adult sample using the same two measures of weight bias. The study design mirrored that used in Study 1, with the only difference being the complexity of some of the sentences. A one-way ANOVA test was run using the instrument version as the grouping variable and using the two explicit measures of bias. An ANOVA is a statistical test used when a researcher wants to look at simultaneous comparisons between three or more groups on the same dependent variable. This test requires a nominal variable as the independent variable, and an interval or ratio variable as the dependent variable. When just the experimental group was considered statistically, participants who viewed the image of the overweight woman had significantly less favorable attitudes toward the subject than those viewing the image of the thin woman. When an ANCOVA test was run to consider gender (and other demographic variables), similar results were found. An ANCOVA test is a statistical test that combines an ANOVA with a regression test. The test essentially looks for changes in the dependent variable based on a nominal grouping in the independent variable with covariates considered statistically.

Analysis was also conducted on the second measure of explicit bias, the more global measure of weight bias. One-way analysis of variance tests indicated significant differences between the five groups. As expected, participants in the control group exhibited greater anti-fat bias than those exposed to the image of the thin man or woman. Significant differences were found between the experimental groups viewing images of thin and overweight individuals and the control group and participants in the thin experimental groups. Thus, it was found that simple exposure to overweight subjects primed individuals to think more negatively about overweight.

Again, in the development of a between-subjects experiment, the analysis could stop at this point because causation had been found – the stimulus material was found to have an effect on participant attitudes about overweight others. However, it would be inappropriate to leave the results at that. For adults especially, the development of a bias against a trait characteristics whether it be weight, gender, age, ethnicity, or religion, is something that develops over time, and that bias certainly develops

with the aid of other outside factors often found in the social world – media exposure, peer influence, and so on. Thus, Study 2 also looked at these other factors to see how or if they were related to increased or decreased levels of bias.

Results from a MANOVA (multiple analysis of variance test, used when there are two or more dependent variables) test examining the relationship of television exposure with experimental version on the two measures of explicit bias suggest there was an interaction effect between the two predictors and each dependent variable. When each dependent variable was considered, greater television viewing was related to higher levels of anti-fat bias; and when the experimental version was considered, participants exposed to the image of the overweight man and woman had even higher anti-fat bias than those who were exposed to the image of the thin man or woman. In order to include other possible predictor variables in the study of bias development, all-inclusive multiple regression (where the criterion is predicted by two or more variables) was used to combine four predictor variables – television viewing, IAT, and the two cognitive processing scales – experiential processing and rational processing. Taken together, the four variables were statistically significant predictors of AFB. Further analysis revealed that, from those four variables, the second cognitive scale measuring experiential processing and IAT were statistically significant predictors of AFB in the presence of the remaining three variables. The all-inclusive model explained 18% of the variance in anti-fat bias. Unexplained variance is an important consideration for mass communication researchers, and it remains one of the weaknesses of our research designs in general, and of experimental design specifically. This point will be addressed in greater detail below.

Findings from both studies suggest that the correlates of anti-fat attitudes may lie in a myriad of factors including individual and social factors, ideology or cultural norms, and media exposure. While the findings across the studies were not completely consistent with regard to the stronger predictors of bias, a few of the factors under investigation were significant across the two studies. The difference in findings could be attributable to the samples themselves – one used children and the other used adults – a design flaw, or because of the likelihood of adults or older children being less willing to admit bias in an overt way.

Of importance in both study findings was the media exposure factor. Whether considered via time spent with the media or by exposure to specific content (thin-ideal content, animated versus live-action programming), time spent viewing entertainment television was a significant predictor of negative attitudes toward overweight. This was found when considered with the experimental version and when considered in isolation. For example, when just the experimental conditions were tested with the dependent variables, a significant relationship was found suggesting that the manipulations did cause an effect in bias. However, when the manipulations (independent variable) were considered along with other variables such as media exposure, a causal relationship was still found as the amount of and type of media exposure also predicted greater weight bias. The social environment, which included household dieting behavior and self-perception as it relates to body

image, was also a strong predictor of increased or decreased levels of bias in both studies.

While findings from both studies resulted in a desired outcome – the stimulus material had an effect on participant attitudes about overweight – neither study was without limitations. Furthermore, even with the desired outcome in each study, I cannot say with certainty that the results are a product of exposure to the stimuli, even though the procedures followed should allow me to come to that conclusion. Such is the nature of experimental design in media studies research. Even if a study has been carefully designed and implemented, statistically our results often look like nonresults to scholars outside of the discipline.

In media studies or mass communication research, the degree or amount of unexplained variance is often quite high. It would not be unusual to find a study reporting an unexplained variance at 75–85%. Unexplained variance is the part of the variance that cannot be attributed to specific causes. For example, in Study 2, I reported that, using four different factors, 18% of the variance was explained, which means that 82% was not. Quite frankly, I was pretty excited with the 18%. In a research world that deals with social factors, we simply cannot statistically control for everything. However, using the two studies described above, the goal is to identify ways in which error and study design problems can be addressed in advance.

Design Problems Specific to the Case Study

Procedures

Both studies used an online instrument containing the stimulus material and measures of independent and dependent variables. While it was convenient to use an online instrument, it meant that participants could easily skip ahead to questions or go back to other questions and change their answers. While the children were in a lab, the lab did not resemble a traditional research lab where extraneous noise and other distractions could be eliminated. Participants in this study sat next to other children and were able to view the stimulus image others were viewing. They quickly realized that they might be answering different questions, and this led to all kinds of possible corruption with the data. From a procedures perspective, it would have been much better if I could have collected data from each child participant individually. Had I been allowed to follow that procedure, however, I would probably still be collecting data as it took roughly one hour for each participant to complete the study. To correct for corruption of the data, I deleted all responses from participants who appeared to be too distracted to participate in the study. This reduced the N from over 1,000 to 601.

In the study with adults, participants were sent a link via email and could complete the study at any time and in any place. Again, while this might have been convenient

for participants and the researcher, there were many factors outside of the lab environment that could not be controlled. For example, participants could have been viewing a television program containing many thin-ideal characters while participating in a research study about weight bias. If that were the case, the viewing of thin-ideal media could have been what caused increases in weight bias rather than viewing an image of an overweight subject. Furthermore, adult participants could have clicked forward and backwards through the instrument or could have hit the link to the instrument more than once, and possibly seen several different versions of the stimuli – there was no way to insure that only one image was viewed. The procedure did allow for data collection in a short period of time, but the nature of those procedures meant that there could easily be threats to the internal and external validity of the study.

Confounding Variables

For both studies, a pilot test was conducted to select the images used for the stimulus material. Despite this, it is possible that participants in both studies had a pre-existing bias against individuals of another gender, race, or age. For both studies, White subjects were selected, and four experimental groups were used so that two groups could use a male subject and two groups a female subject. The 2 in the 2×5 experiment meant that gender was one of two factors considered. Statistical tests indicated no bias based on in-group/out-group selection, meaning there were no statistically significant differences for female participants viewing the female subject or the male subjects viewing the male subject. However, an implicit bias against overweight females could still be present, even if it was not evident statistically. Finkelstein, Frautschy Demuth, and Sweeney (2007) report that in workplace and social settings, bias against overweight women is stronger than it is for overweight men. In a mediated context, overweight male characters are often portrayed as funny whereas overweight women are portrayed as unhappy, depressed, unable to obtain a date, and constantly dieting (Ata & Thompson, 2010). This bias against overweight females might be present on a societal or even ideological level and therefore be difficult to measure or control for statistically.

A confound is something that varies along with the independent variables that inhibit the researcher's ability to say what caused the variation in the dependent variable. Other possible confounds with the present study are variables not included as independent variables, covariates, moderating variables, or mediating variables. Media exposure, especially exposure to thin-ideal media content, is a possible confound. There are other factors that may have resulted in elevated levels of bias against overweight, but these intangible variables can be difficult to measure. For example, as with other forms of bias, stigma, or prejudice, bias against overweight is often learned. A child who lives in a household with a parent who speaks negatively about people of different races may learn to think negatively about that race. The same

could be said about bias against overweight. The word “fat” has a negative connotation. If a child lives in a household where a parent, sibling, or other individuals use the word “fat” in a negative context, the child could learn to see fat in negative terms. Results from the IAT (in both studies) suggest that the majority of participants did associate overweight with negative adjectives, but I am unable to assess why. However, this implicit bias can certainly be correlated with explicit bias (as evidenced in both studies), and therefore merits a study limitation simply because the development of that bias is simply too difficult, if not impossible, to explain.

Wimmer and Dominick (2006, p. 235) state that researchers must “ensure the internal validity of their research by controlling for the effects of confounding variables (extraneous variables) that might contaminate their findings.” In theory, these confounding variables can be controlled through the environment, through experimental manipulations, through the design itself, or through the assignment of subjects. In practice, even if these procedures are implemented, it remains difficult to control for all possible extraneous variables that might have an influence on the dependent variable.

Random Selection

Participants in both studies were randomly assigned to one of five groups – four experimental groups and one control group. Random selection means that every person in the sample has an equal chance of selection for any of the groups. The beauty of randomization, beyond so many other factors, is that the variables to be controlled are distributed in approximately the same way in all groups. Simple random assignment is more challenging when dealing with studies outside of the lab environment. For example, child participants in Study 1 simply drew a number from a basket, and adult participants in Study 2 were randomly sorted into one of five groups based on a randomization program built into the study. The procedure used to randomize the stimulus photograph viewed by all participants was indeed random, so one might think that randomization means the study was probabilistic. Two key types of sampling are used in empirical studies – probability sampling and nonprobability sampling. Each has its own strengths and weaknesses. Because participants in the studies described were randomly assigned to experimental or control groups, one might assume the study was probabilistic. However, the original sample in both studies was a convenience sample, which means that the entire sample was a nonprobability sample and the results are not as generalizable as they might otherwise be.

Sample/Cell Size

While random sampling has many advantages, one issue with randomization is that if the sample size is small, there is a higher risk of the groups not being equivalent.

For example, Study 1 had 601 participants in the final sample, but in order to look at factors such as participant gender, grade, and ethnicity, the sample size would have needed to be double the size in order for the sample size within each smaller cell to be appropriate. For example, the approximately 600 participants were divided into 10 groups (gender (2) $\times$ by instrument version (5)), leaving approximately 60 participants per cell. This cell size is large enough for statistical power; however, if I wanted to look at the responses by grade, that number would be divided by four, and I would wind up with a cell size that was too small to yield statistically significant results ($n = 5$). The lesson to be learned from this is to carefully consider the statistics that will be run in advance, and then think through the data analysis to insure an appropriate cell size is achieved.

Effect Size and Statistical Power

The power of the statistical test is determined by the significance criterion, the precision of the sample criterion, the precision of sample estimates, and the sample size (Sawyer & Ball, 1981). More simply, statistical power is the probability that a statistical test will correctly reject the null hypothesis. In media studies and mass communication research (and many other types of research), most readers understand that when $p < .05$ is seen, it means there is less than a 5% chance that the researchers have made a Type 1 error (a false positive) in their conclusion. The higher the power, the greater the chance that the decision or assumption is correct. In order to achieve a higher power, the level of significance, the sample size, and the standard deviation of the population or the sample will be relevant. Study 2 included 276 participants randomly sorted into one of five groups and then that number was cut in half for the sort by gender. If the groups had been equal, a cell size of 27 would have been high enough for statistical power; however, because I had more female participants than male participants, my cell size for men across the five groups was too small to run statistical tests.

In addition to having to be concerned with statistical power, researchers using experiments must also consider a study's effect size. Effect size describes the magnitude or strength of a relationship between two or more variables in the population. If other design factors are controlled for properly, the greater the effect size, the greater the power (Sawyer & Ball, 1981). Effect size should be one of the first factors considered when designing a study. Effect size can also be explained via explained (or unexplained) variance. With any data set and with any type of statistical test, variance (a characteristic of the data set and one that describes the range of responses within a data set) is of key importance because a researcher looking at data patterns or trends wants there to be diversity or a range in the responses but not so much range that no statistically significant differences can be found. The higher the explained variance relative to the total variance, the greater the effect of the variable in question. For example, if a researcher were to predict that exposure

to thin-ideal media would cause greater anti-fat bias, the higher the explained variance, the more confidence the researcher would have in asserting that X caused Y. Given the nature of the discipline, our effects sizes are almost always small. Within the discipline, we know and understand that, but when our work is viewed by scholars from other disciplines, they might scoff at what we report to be a significant finding. While there is little we can do to control effect size or unexplained variance within our discipline, it is important to teach our graduate students, who often learn statistics in other disciplines, not to be disappointed with our comparatively small effect sizes.

Post-Test Only Data

Research methods books teach us about the variety of ways an experiment can be conducted. We hear about designs such as the Solomon four-group design, the pretest–post-test–control group design, and the post-test only design. In an ideal scientific world where humans are not involved, the Solomon four-group design or the pretest–post-test designs are the most appropriate ways to assess the effect of the independent variable on the dependent variable. These designs allow for a baseline measure on the dependent variable, therefore allowing the researcher to observe any change following exposure to the stimulus material. In a simple experiment, a researcher could be interested in determining whether exposure to violent television content would predict or cause aggressive thoughts in young children. If a very simple experiment were to be designed to test this, child participants would be randomly assigned to the experimental group who would view violent content or a control group who would view humorous content or no content at all. The researcher would measure aggressive thoughts in all participants following exposure to the content and then make comparisons between the two groups. If the theory predicted that violent content would likely produce or cause aggressive thoughts, the researcher could observe a greater incidence of aggressive thoughts from the experimental group than from those in the control group. In this case, control group participants act as the baseline measure of aggressive thoughts as they were not exposed to the content that would (hypothetically) produce aggressive thoughts.

The logistics of this design are another issue entirely. Again, when collecting data outside of a lab setting (or even in a lab setting), the likelihood of getting a participant to return to the study for a second round of data collection is low. The proportion of individuals who return to participate in a study is less than half, and if the study is long or the lab environment difficult or inconvenient to return to, the return rate is even lower. In a between-subjects design, pretest data would allow the researcher an opportunity to have a baseline measure of the dependent variable prior to exposure to the stimulus and then have a repeat measure of the dependent variable following exposure. While the objective of the between-subjects design is to

compare responses on the dependent variable between groups, it is never a bad idea to be able to see if there is a change in the dependent variable via the within-subjects design – that is, by comparing a subject's pretest and post-test scores on the dependent variable. If this procedure could be followed, it would provide the researcher with a greater opportunity to say with certainty that exposure to the stimuli caused the specific outcome under investigation.

In neither study did I have pretest measures. In an ideal world, I would have collected pretest data, given participants a few days, and then had them return for the second part of the experiment. However, the logistics of my two studies did not allow for that, and thus, I can only report findings from the post-test study.

How Between-Subjects Designs Can Be Used in Media Studies Research

Media studies and mass communication researchers have a wealth of opportunity to utilize between-subjects experimental design as a means of assessing or determining the effect of specific media content on cognitive, affective, or behavior outcomes. Researchers interested in political communication might want to better understand how or if a political ad is more or less effective with a visual. A between-subjects design could be developed in a way that used a text-only ad, a visual-only ad, a text and visual ad, and a control group. If the researcher were interested only in the effect of variable X (the independent variable), on the dependent variable, attitudes toward a specific candidate, the straightforward design described above would be appropriate.

However, it is possible the researcher might realize that an individual's political orientation could also influence attitudes toward a specific candidate, regardless of the experimental group sampled into. In order to design this type of study, the researcher could design a 3×4 factorial design. The 3 would allow a researcher to group participants by political orientation (liberal, moderate, or conservative) or by political party (Republican, Democratic, or "other" – acknowledging that this factor could be much larger in size) and then by the four groups in the experiment (three experimental groups and one control group). While this type of design still would not be without its limitations, the simple design would allow for (1) comparisons across experimental groups, and (2) comparisons across experimental groups based on political orientation. The 3×4 factorial design allows for the comparison of two independent variables on a single dependent variable, and the proposed design would allow a researcher to statistically test the two IVs on the DV. This is just one of many examples of the way a study could be developed using between-subjects experiments.

As researchers, we are taught to spend some time reading through studies relevant to our interests, to acquire an understanding of the theoretical framework(s)

appropriate for investigating our subject of interest, and from there develop a hypothesis or research question that predicts a relationship between two variables. The research question or hypothesis will dictate the type of design needed. A between-subjects design is a way of avoiding the carry-over effects of a within-subjects design, whereby with random assortment into all groups, the researcher can state with some authority that the stimuli had a specific effect on the dependent variable. The between-subjects design, sometimes called the *independent measures design*, is beneficial because it limits participants to a single treatment or exposure group. This type of design eliminates participants “learning” what is being asked of them, and it further eliminates participants dropping out or checking boxes out of boredom.

The underlying assumption of the between-subjects approach is that Group 1 and Group 2 are different levels of the same factor. Using the political advertising example above, the 3×4 factorial design meant that participants would be sorted by three groups of political orientation and sorts into four groups associated with the experiment (text ad, visual ad, text and visual ad, or no ad). If it is determined that a between-subjects design is the most appropriate for the study questions, it is prudent for researchers to then consider the following questions:

- 1 What other variables might be related to the outcome variable?
- 2 Is there enough variation between experimental groups that an effect can be found?
- 3 Is there enough variation between the experimental and control groups that an effect can be found?
- 4 How large must the sample size be in order for statistical significance to be found?
- 5 What is the most appropriate method for randomizing participants into the respective groups?
- 6 Have the necessary steps been taken to insure that participants within the group are similar, that is, there is an oversampling of women in one group and an oversampling of African Americans in another group?
- 7 What types of statistics are appropriate given all of the variables being measured?
- 8 Does the design allow the researcher to measure what he or she intends to measure?

Experiments are the primary tool for studying and understanding causal relationships. In media studies and mass communication research, causality is an important tool, as at least a third of the research in the field is related to the media’s effect on audiences (McDonald, 2004). As Babbie (2010, p. 249) explains, “the chief advantage of a controlled experiment lies in the isolation of the experimental variable’s impact over time.” Though many researchers are critical of experimental designs because of the artificiality associated with them, experiments remain a staple in mass communication research and media studies.

Between-subjects experimental designs are an important tool in scholars' wheelhouse, and with knowledge about the limitations of the design within the discipline, solid, meaningful research can be conducted. Iyengar, Peters, and Kinder (1982) discussed experiments in the context of the role of television news programs on viewers' attitudes and beliefs. They report that the consequences of exposure are "not so minimal" and that earlier assumptions about media effects were indeed on the mark. This is something Lippmann alluded to almost a century ago. As Iyengar, Peters, and Kinder (1982, p. 855) conclude: "Fifty years and much inconclusive empirical fussing later, our experiments decisively sustain Lippmann's suspicion that media provide compelling descriptions of a public world that people cannot directly experience."

Experimental design remains one of the most important methods in empirical research in mass communication and media studies. Researchers interested in media effects on a broad range of topics can use experiments to test the influence the media have in shaping individuals' knowledge, attitudes, and behavior. While they may be difficult to design, properly conducted experimental studies yield results that enable us to better understand the role the media play in our lives.

Using a Mixed Approach to Content Analysis

The Case of Apologetic Rhetoric in the Modern Presidency

Rico Neumann and Kevin Coe

ABSTRACT

This chapter demonstrates the process and utility of an approach to content analysis that blends computer-assisted content analysis (CCA) with traditional manual coding. It does so in the context of modern presidential rhetoric, shedding light on presidents' use of apologetic rhetoric in their public communications to audiences abroad over the past eight decades. We outline the steps that are necessary to undertake a mixed approach to content analysis, and discuss the advantages and disadvantages of such a method. We argue that although CCA represents a useful tool to process large quantities of text, its use can sometimes obscure important nuances in the discourse. Conducting a complementary manual coding can highlight many of these nuances, making the mixed approach a fruitful technique in many cases.

Within a few months of taking office in 2009, President Barack Obama traveled abroad to announce his presidency to the world and to begin rebuilding some of the relationships that his predecessor's administration had strained. On April 3, for example, he was in Strasbourg, France, where he critically referred to earlier times when "America has shown arrogance and been dismissive, even derisive."¹ The

following day, Obama was asked about America's place in the world, to which he responded:

The fact that I am very proud of my country and I think that we've got a whole lot to offer to the world does not lessen my interest in recognizing the value and wonderful qualities of other countries, or recognizing that we're not always going to be right, or that other people may have good ideas, or that in order for us to work collectively, all parties have to compromise, and that includes us.

Two days later Obama addressed the Grand National Assembly of Turkey in Ankara, where he characterized relations between the United States and Turkey as follows:

I know there have been difficulties these last few years. I know that the trust that binds the United States and Turkey has been strained, and I know that strain is shared in many places where the Muslim faith is practiced. So let me say this as clearly as I can: The United States is not and will never be at war with Islam.

Obama's self-critical rhetoric did not go unnoticed. US journalist James Kirchick, for instance, wrote in the *Los Angeles Times* that the president had undertaken a "grand global apology tour" during which he was guilty of "flagellating the nation he leads" (Kirchick, 2009).

President Obama's words, whether a true apology or not, are but one example of the brand of apologetic rhetoric that is common in the political arena. Indeed, political leaders' statements of remorse for historical transgressions, injustices, and wrongdoings, have been an essential part of many societies and cultures (Barkan, 2000; Digeser, 2001; Negash, 2006; Weiner, 2005; Yamazaki, 2005). In the context of the US presidency alone there are numerous examples. Among the most widely known are George W. Bush's attempt to restore national reputation after tragic incidents at the Iraqi prison Abu Ghraib and the detention camp in Guantanamo Bay; Bill Clinton's attempts to repair his personal image after the Monica Lewinsky scandal; Ronald Reagan's public statement on his role in the Iran-Contra affair; and Richard Nixon's response to Watergate. Given these and other high-profile instances, it is not surprising that there has been much recent discussion about the "age of apology" (Brooks, 1999; Cunningham, 1999; Gibney, Howard-Hassman, Coicaud, & Steiner, 2008; Govier, 2002; Harris, Grainger, & Mullany, 2006), accompanied by labels such as a "sorry world" (Nobles, 2008), and "America the apologetic" (Brookhiser, 1998). The body of research on apology is growing rapidly (Gibney et al., 2008; Negash, 2006; Nobles, 2008).

Notably, the literature on apologies – and public apologies in particular – is almost exclusively qualitative in nature, drawing on detailed analyses of individual cases or single presidencies (e.g., Edwards, 2008a; Harter, Stephens, & Japp, 2000). Very few scholars have investigated the topic using quantitative methods or mixed methods approaches (notable exceptions are Blatz, Schumann, & Ross, 2009; Kampf, 2009a).

Given this imbalance in the literature, apologetic rhetoric is a particularly useful context in which to demonstrate the utility of a *mixed approach* to content analysis, one that precisely specifies quantitative trends in large quantities of text by blending computer-assisted content analysis (CCA) with traditional manual coding. In explaining and demonstrating this approach, this chapter also addresses several unanswered questions about apologetic rhetoric in one key context: the modern American presidency. Toward this end, we first briefly review the literature on apology and offer a conceptual definition of “apologetic rhetoric.” We then explain our method in some detail, so as to fully outline the steps that are necessary to undertake a mixed approach to content analysis. We then present the findings of our analysis, before concluding by considering the advantages and disadvantages of this particular approach to content analysis.

Apologetic Rhetoric

At the interpersonal level, many people do not even notice how often they use the word “sorry” to help undo a hurtful act. People apologize for myriad reasons. Whatever the motive, the goal is often to heal the relationship between the victim and the wrongdoer and to repair the wrongdoer’s image (Benoit, 1995; Smith, 2008). Just as important as interpersonal apologies are those on a national or international level, where a genuine apology can be of profound value for the future relationship between the wrongdoer and the wronged (Lazare, 1995). The act of apologizing, however, becomes more complex (and therefore also less frequent) when apologies are offered on behalf of a group, institution, company, or nation (Tavuchis, 1993). Not surprisingly, literature on public apologies is more limited than writings that deal with the interpersonal sphere, yet the body of research has been growing rapidly throughout the past decade. According to Lind (2008), a great number of activists and academics have contributed to an increasing body of scholarship on contrition and apologies on the international level.

As a response to historical transgressions, leaders around the world have offered public apologies in an effort to heal relations and seek reconciliation; for example, Japan apologized to South Korea for military invasions before and during World War II (Yamazaki, 2005); Germany apologized for its colonial past in Namibia (Jamfa, 2008) and for the Holocaust (Negash, 2006); and Kofi Annan apologized for the United Nations’ inaction during the Rwandan genocide (Edwards, 2008b). Several examples from the American context have already been noted. In all cases, such public apologies represent rhetorical attempts to (re)negotiate “membership in a group, community, nation, or humankind” (Towner, 2009, p. 431). National leaders, whose words carry particular weight, thus act as mediators by representing the interests of the national community on the international stage. As Kellerman (2006, p. 74) states, “a leader’s apology is a performance in which every expression matters

and every word becomes part of the public record.” Moreover, the willingness to offer a public apology is not only of high emotional value and may raise “the moral threshold of a society” (Brooks, 1999, p. 3), but it also bears a clear strategic value for the wrongdoer (Lazare, 2004).

Apologetic rhetoric can take many different forms and invites a variety of rhetorical approaches, strategies, and tactics. Specifying its usual form is made difficult by a lack of systematization and the explosive growth in literature on public apologies (Benoit, 1995). An early conceptual distinction was made between “apologia” and “apology.” The Greek term *apologia* originally appeared in Plato’s work *Apología Sokrátus* and refers to the speech Socrates gave in defense against the accusations that were brought against him. Hence, it has been framed as a defensive rhetorical response to an attack on one’s character and is therefore primarily focused on the self, to restore a damaged image (Ware & Linkugel, 1973). Despite its etymological similarity, an “apology” typically occurs without any defense and is “a form of self-punishment that cuts deeply because we are obliged to retell, relive, and seek forgiveness for sorrowful events that have rendered our claims to membership in a moral community suspect or defeasible” (Tavuchis, 1993, p. 8).

A notable effort to systematize the field was undertaken by Benoit (1995), who proposed a theory of image restoration consisting of five strategies which rhetors can rely on when faced with a crisis: denial, evading responsibility, reducing the offensiveness of the event, taking corrective action, and mortification. While denial – often accompanied by some form of blame shifting and self-defense – is most similar to the traditional *apologia* rhetoric, a mortification strategy usually strives for a true apology. Similarly, Kampf (2009a, p. 2258) focuses on the discourse of minimizing responsibility by utilizing “creative forms of apologetic speech.” Based on a detailed discourse analysis of apologies made in the Israeli public sphere, he demonstrates a variety of rhetorical tactics which can be grouped into four main categories: blurring the nature of the offense, compromising the apology’s performative verb (e.g., “sorry” versus “apologize”), questioning the identity of the offender, as well as questioning the identity of the offended.

In a narrative synthesis, Towner (2009, p. 457) argues that although the extant literature provides many unique and detailed analyses, it “may have the unintended consequences of alienating scholars who might otherwise learn from and support each other’s research.” In other words, the body of research has grown so rapidly that scholars following one approach tend to overlook important research from the other end of the spectrum. One way to bridge that gap is to embrace a broader conception of apology, which takes the many different creative forms of apologies into account. Various efforts have been made to describe (and prescribe) the “perfect” or “true” apology (Kellerman, 2006; Lazare, 2004; Tavuchis, 1993). However, given that conflict situations take multiple forms and offenses are perceived differently, different rhetorical strategies are required. With this in mind, we draw on previous conceptualizations of apology and *apologia* to offer a broad definition of *apologetic rhetoric*.

Our goal in doing so is to help bridge the gap between the extant literature, which is largely qualitative and specific, and the broad patterns that might exist across apologies for a range of different wrongs across an extended period of time. The large body of qualitative and normative writings is important in that it sheds light on specific cases. Still, broader understandings that might be gleaned from considering apology more broadly are needed. With this goal in mind, we define apologetic rhetoric as *a strategic and value-driven communicative process in which an apologizing entity publicly and responsibly acknowledges a past misdeed, negotiates a shared understanding of the conflict situation with the harmed party, and ultimately asks for forgiveness.*

Several elements of this conception are noteworthy. That apologetic rhetoric is *strategic* and focused on *responsibility* highlights that a public figure may employ a variety of rhetorical tactics in order to minimize – or “democratize” – the degree of responsibility (Kampf, 2009a, 2009b). It is *value-driven* because it is rooted in basic moral values that are reaffirmed, which allows an individual, a community, or a nation to grow morally and re-establish the moral balance and relationship between victim and offender (Hearit, 2005). In the political realm, it may also serve as a “platform for announcing new policy directions” (Nobles, 2008, p. 111). Apologetic rhetoric takes place in *public* because it is a collaborative process and shapes the discourse between national and international leaders, citizens, activists, interest groups, and the media. It seeks to *negotiate* a mutual (re)interpretation of the crisis situation “rather than an inherently psychological or scripted response to a conflict” (Paul, 2007, p. 4) in order to (re)interpret membership between the involved parties (Nobles, 2008). In a similar manner, Tavuchis (1993, pp. 57–58) notes that apologetic rhetoric “presupposes cognitive and evaluative congruence in the form of shared definitions of the violation, its severity, history, and implications.” In contrast to previous conceptions of apologia and apology, this broader definition of apologetic rhetoric allows for a diverse collection of apologetic expressions to be examined over time – a task that certainly invites CCA but also relies on the merits of a traditional approach via manual coding.

Research Questions

The above discussion makes clear the need for a broader analysis of apologetic rhetoric. We took a step in this direction by examining eight decades’ worth of presidents’ apologetic rhetoric. Our focus was the American presidency because US presidents are key figures in the nation and the world, and their apologetic rhetoric therefore has great potential for attention and impact. To keep the scope manageable, we focused particularly on situations where presidents face a foreign audience. Such situations may require a higher degree of rhetorical sensitivity, especially when relations with the nation in question have been strained. Compared to other addresses,

speeches abroad are also the most likely to include some form of apologetic rhetoric. Four specific questions guided our analysis:

- RQ1 To what extent have presidents used apologetic rhetoric in their public messages given to foreign audiences?
- RQ2 What forms of apologetic rhetoric have presidents used in their public messages given to foreign audiences?
- RQ3 How does the use of apologetic rhetoric differ in communications that are high or low in “message control”?
- RQ4 To what extent have presidents used common rhetorical strategies in their public messages given to foreign audiences?

Planning a Mixed Approach to Content Analysis

Three basic steps are necessary in conducting a mixed approach to content analysis: (1) selecting an appropriate body of text; (2) administering the computer-assisted content analysis; and (3) administering the manual content analysis. This section details each step in turn.

Selection of Text

We made two choices to narrow the scope of texts for this analysis. The first, discussed above, was to focus on presidential speeches delivered abroad – a context in which apologetic rhetoric often occurs. The second was to limit our analysis to the modern presidency, which scholars have generally defined as beginning with the presidency of Franklin D. Roosevelt in 1933. This period of analysis is useful because the presidency changed significantly beginning with Roosevelt. Federal and national power grew, as did the United States’ worldwide recognition as the leader of the free world as well as advocate of human rights and free markets, particularly highlighted during the Cold War and beyond (Greenstein, 1998, 2004; Medhurst & Brands, 2000). As Leuchtenburg (1988, p. 7) notes, “by almost all accounts, the presidency as we know it today begins with Franklin Delano Roosevelt.” Thus starting with Roosevelt allows for 13 presidents to be included in the content analysis but retains some consistency in the cultural context in which each president governed.

Our corpus of presidential communications therefore consisted of 2,186 messages delivered abroad, beginning with Roosevelt’s visit to Haiti in July 1934 and ending with Obama’s visit to Prague, Czech Republic, in April 2010. To identify foreign speeches, we first consulted the official website of the US Department of State (<http://history.state.gov/departmenthistory/travels/president>), which provides an overview of all visits abroad for every president included in our analysis.

Using information about the specific date and country provided in these lists, we were able to locate and retrieve the transcripts from the National Archives' "Public Papers of the Presidents" (n.d.), the comprehensive record of presidential communications. For example, once we found out that Obama visited Egypt on June 4, 2009, to deliver his address "A New Beginning" at Cairo University, we could easily identify the corresponding transcript. Additional remarks delivered during his stay in the country were retrieved as well (in that case, an interview with foreign journalists and remarks prior to a meeting with then President Mubarak). The procedure was repeated for every foreign visit undertaken by each of the 13 modern presidents.

Notably, this sampling approach excluded some speech acts that are known to include formal apologies, such as Congressional statements (e.g., the apology for the overthrow of the Hawaiian kingdom) or presidential speeches given to groups of people within the nation's borders (e.g., apologies for Japanese American internment during World War II). Also excluded were informal remarks during the president's vacations, brief remarks made on arrival at or departure from foreign airports, and informal exchanges with reporters abroad. The final corpus thus consisted of the following message types:

- First, perhaps one of the most significant speech occasions, is a major address given to a foreign legislative body (assemblies or parliaments), which accounted for 5.1% of all messages considered in this analysis ($n = 111$). Examples included Carter's address before the Israeli Knesset in March 1979 and George W. Bush's address before the Japanese Diet in February 2002.
- Second, presidential remarks during state dinners are often given in honor of the host, usually the head of state or executive leader. These were once famous speech occasions (particularly during the Cold War), but the significance and frequency with which presidents communicate in such forms have decreased markedly. However, due to generally tight time schedules these are sometimes the only major remarks a president delivers while visiting a foreign nation. For example, while the early toasts made by Roosevelt were often only brief statements relying on rather typical rhetoric for such occasions, the toasts offered by Carter were lengthy speeches dedicated to foreign leaders, and therefore worthy of exploration. Across all presidents, such speeches accounted for 13.7% ($n = 299$). Examples included Nixon's remarks at a state dinner hosted by the shah of Iran, Mohammad Reza Pahlavi, in Tehran in May 1972, and Reagan's remarks at a dinner hosted by Queen Elizabeth II at Windsor Castle during his visit to the United Kingdom in June 1982.
- Third, no less significant, but more numerous are presidential speeches and remarks made to foreign citizens in public places (e.g., city halls, universities, market squares). Often, those follow meetings with the head of state and are intended to address a larger audience more directly. In our study, those accounted for 28.8% of all presidential communications abroad ($n = 629$). Examples included

- Kennedy's 1963 and Reagan's 1987 speeches in front of the Brandenburg Gate in Berlin, Germany, and Obama's address at Cairo University in Egypt in June 2009.
- Fourth, major documents, such as (joint) statements and declarations released during or after a president's foreign visit, were considered for analysis. Previous research suggested that apologies (and other expressions of regret) are sometimes offered intentionally as brief, written statements only – in order for presidents to bypass such comments in their speeches (see Nobles, 2008). Written messages account for 14.1% of all messages ($n = 309$). Examples included Clinton's joint communiqué on the Summit for Peace and Prosperity, which was released in March 1998 in Uganda, and G. W. Bush's statement calling for a new strategic partnership with Pakistan in March 2006.
 - Fifth, foreign press conferences, town hall meetings, and interviews with foreign journalists were subject to analysis. These contexts differ from others in that speakers are forced to be less deliberate and strategic in the words they choose (by virtue of the fact that they take place in an interactive, two-way communication forum). For example, in their conception of major presidential addresses, Coe and Neumann (2011, p. 733) delineate "message control" as a major criterion by referring to situations where the president has full control over the message; that is, "the words that a president speaks are a matter of choice, usually carefully planned and rehearsed well in advance of the speaking event." This loss of "message control" in news conferences may lead presidents to employ different rhetorical tactics from what they would use in the more deliberate speech acts listed above. Press conferences and interviews with the president accounted for 26.4% of all presidential communications abroad ($n = 577$). Examples ranged from Roosevelt's famous World War II press conferences in Casablanca (January 1943) and Yalta (February 1945) to the above-mentioned news conference of Obama in Strasbourg, France, in April 2009.
 - Sixth, although not given on foreign soil, speeches to the United Nations General Assembly or the Security Council (in New York City) have become a regular (i.e., annual) speech tradition for the US president since Reagan. Given that in those speech situations the president also responds to concerns of the international community in general and of foreign leaders representing their nations in particular, these speeches were considered worthy of analysis. UN speeches accounted for 2.9% of all presidential messages considered in this study ($n = 64$). Examples included Truman's first address to the UN General Assembly during its opening session in October 1946, and G. W. Bush's "An Appeal to Muslims" speech in September 2006.
 - Lastly, speeches given on foreign soil also encompass remarks directed to Americans living abroad (e.g., embassy staff, troops, US communities) and to the American audience at home (e.g., radio addresses to the nation). Those messages accounted for 9% of all presidential communications abroad ($n = 197$). Examples included Ford's remarks to American troops stationed in South Korea in November 1974, Clinton's remarks to military personnel at Ramstein Air Base, Germany,

in May 1999, and G. W. Bush's speech to US troops in Baghdad, Iraq, at a Thanksgiving dinner in 2003.

Administering CCA

At the outset of the study, all the necessary transcripts were compiled in a raw text file (e.g., a Word document) and organized around simple descriptive variables that depended on the goal of the analysis (in our case, this included date, president, location/ country, and message type). This information – called the “control sequence” – was entered manually for every transcript as a string of external variables (separated by dashes) beginning with a four-digit, ascending sequence number that each text unit received at the outset (the length of the sequence number depends, of course, on the number of texts the researcher considers for analysis). The control sequence was placed before each transcript so that the raw text in the entire file could be easily separated into text units. This process is time consuming, but manually entering these external variables allows researchers the flexibility of more varied analysis (e.g., by comparing Democrats and Republicans, distinguishing between written and spoken communication, grouping countries into regions). Additionally, certain transcripts required some pre-editing to remove all substantive nonpresidential content (such as lengthy responses of another country's leader in a joint press conference).

Once the raw text file was compiled, the content was subject to computer-assisted content analysis using the software TextQuest,² which allows processing of large quantities of text. This software requires that the researcher develop another file in the form of a dictionary of search patterns that the computer will retrieve from the entire text file once identified. For the present study, relevant semantic units included in our dictionary file (in the following referred to as *lexemes*) were as follows: amends, apology, atonement, blame, blunder, compunction, confession, contrition, deficiency, deplore, error, excuse, expiation, fail, fault, flaw, forgiveness, guilt, inadvertence, injustice, lapse, misconduct, misdeed, misdemeanor, mistake, pardon, penance, penitence, plea, reconciliation, regret, remorse, repentance, ruefulness, shame, shortcoming, sin, sorrow, transgression, and wrongdoing.

Words appear in various inflected forms (as noun, verb, adverb, adjective, etc.). We therefore focused on a word's morphological stem (or lemma) to allow for its linguistic derivatives. For instance, instead of entering the term “apology” into our dictionary file, we used the root morpheme “apolog-,” which captures the noun “apology,” its plural form “apologies,” its adjectival form “apologetic,” the verb “apologize” (and given its regular verb form, its past and future tense too), its adverbial form “apologetically,” and related nouns such as “apologist(s)” and “apologia.” In doing so, the analysis can be refined and focused on the unit of meaning (semantic content) rather than a unit of speech (predefined words).

Additionally, we consulted the online Merriam-Webster dictionary to retrieve a term's definition and perform a search for synonyms and related words. For example,

Merriam-Webster provides two definitions of an apology: “an explanation that frees one from fault or blame” and “an admission of error or discourtesy accompanied by an expression of regret.” Hence, the terms “fault,” “blame,” “error,” and “regret” subsequently became subject to the same thesaurus search and their stems were entered into the dictionary file. Other suggested surrogate and related terms for “apology” were “plea (of guilty),” “atonement,” and “confession,” among others. Admittedly, the thesaurus search provides many more synonyms and related words, but researchers who aim to conduct a computer-assisted content analysis of a significant corpus of speeches are forced to make certain practical decisions. For example, the words “reason” and “justification” were suggested surrogate terms for “apology,” while “responsibility” and “accountability” were offered as a substitute for “blame” by Merriam-Webster. Entering the stems of those terms would make the analysis less precise because they capture a large number of rhetorical moments that are not related to apologetic rhetoric. To be clear, then, these terms are not exhaustive, but rather emerged as the most common ways public officials acknowledge their mistakes and verbalize their apologies, based on their presence in the extant literature, a thesaurus search for relevant synonyms, and several readings of randomly selected presidential speeches prior to conducting the CCA.

The main purpose of developing such dictionaries is twofold. First, in analyzing a set of transcripts it provides some initial trend data based on the usage of specific terms (e.g., to assess the overall use of the lexeme “apology” in presidential rhetoric) or frequency of the variables entered into the string (e.g., in our case the frequency with which presidents have traveled to certain countries). Second, the method provides the opportunity to narrow the search down to relevant content – those messages that include some form of apologetic rhetoric. In other words, a certain number of speeches did not qualify based on these exclusion criteria, and thus did not require further analysis. TextQuest makes it possible to locate such key terms within a given text or a set of texts. In addition, it provides contextual information (all surrounding words and sentences called “concordances”) that is clustered around the lexeme. By using such a filter function, a printable output file is created and the manual coding procedure is made manageable.

Administering the Manual Coding Procedure

All remaining speeches were subject to manual content analysis, with the unit of analysis being a single mention of any of the identified lexemes. The coding scheme for this analysis was in part based on previous research and conceptualizations of public apologies (Abadi, 1990; Blatz et al., 2009; Kampf, 2009a) and newly added measures. As mentioned in the preceding section, each text received a number at the outset. Units that qualified based on the filter search via keywords received an additional number (in ascending order). For example, a text may include no such term at all, while another text includes several of the lexemes representative of apologetic

rhetoric. Once those units were identified, one essential criterion for inclusion was to code for *self-reference*, that is, while using the lexeme, presidents refer either to themselves or the United States (e.g., “my fault” or “mistakes we’ve made in the past as a country”) or to another entity (e.g., “guilty nations”). This aspect of the process requires human, rather than computer, judgment. If the latter was the case, the instance did not qualify as self-referential apologetic rhetoric. However, if the former was the case, the following additional items guided the rest of the content analysis.

- *Creative use of tense and conditional form.* Sometimes speakers make use of so-called “non-performative” apologies (Kampf, 2009a). The purpose of this category was to differentiate between actual statements (the act of confession occurs as part of the speech act, or a reference to a past confession is made), and hypothetical situations (including conditional and future tense). An example of the former is “The uncertainty might come from our failure to control and to regulate the arms competition” (Carter, 1979) whereas an example of the latter is “If we, the U.S., have been at fault we stand ready to be corrected” (Eisenhower, 1958).
- *Willingness to engage in self-criticism.* The purpose of this code was to distinguish between instances in which the speaker makes some criticism of the nation (by publicly admitting mistakes or offering an explicit apology) and instances in which the speaker refuses to do so (an explicit refusal to apologize or to acknowledge mistakes). This does not refer to the responsibility taken for the act. Examples are “We shall not be so pious or so hypocritical as to pretend that we have not made mistakes” (Nixon, 1970) with regard to Vietnam, or “Today we rejoice also in another event for which we need not apologize” (Roosevelt, 1943).
- *Use of the lexeme “apology.”* The performative verb “to apologize” is considered the strongest of all forms of apologetic rhetoric and therefore deserves emphasis. This code was used to distinguish between uses of “apologize” and any other form, for example, “I am sorry” or “I regret.” Examples are “I am sorry, I omitted that from my comments” (G. H. W. Bush, 1991) and “To the extent I’ve caused this, I apologize” (G. W. Bush, 2007).
- *Specifying the nature of the act.* The purpose of this code was to distinguish between generic, superficial remarks and specific, clear-cut remarks. Kampf (2009a) proposed this rhetorical strategy to blur the nature of the offense and minimize responsibility. An example of the former is “we make mistakes and we’re not perfect” (Clinton, 1994), whereas an illustration of the latter form is “It’s a shame in America that children getting out of high school cannot read sufficiently” (G. W. Bush, 2002).
- *Specifying the identity of the wrongdoer.* The purpose of this category was to assess whether the offender is mentioned in the discourse or not. The rhetor may use the first-person plural form (“we”) or, to concretize responsibility, may mention the wrongdoer (e.g., “we Americans”), or refer to himself as the principal offender (“I”). Examples from the discourse include “We failed to bring Saddam Hussein back into the family of nations” (G. H. W. Bush, 1992). Examples emphasizing

the nation include “We in the United States have made many mistakes in our relations with Latin America” (Kennedy, 1961). Examples highlighting the speaker include “my failure to avoid mentioning several immediate problems that are troubling the U.S.” (Eisenhower, 1960).

A total of 2,362 potential instances of apologetic rhetoric were identified by TextQuest. However, this number also included remarks uttered by reporters or hosts (mostly during interviews or press conferences). Recall that substantive remarks by other foreign leaders (which are typically part of the speech files released by the *American Presidency Project*) were already excluded *before* conducting the CCA. However, the typical question and answer form of interviews and news conferences made it somewhat difficult to exclude *all* nonpresidential content at the outset of the study. Moreover, important contextual information may have been lost in so doing. To clean the data from those instances, an analysis of the TextQuest concordances – each consisting of 300 characters in our case, that is, 150 characters occurring before and after the particular lexeme – made it possible to identify those apologetic lexemes that were not spoken by a president (we considered 300 characters to be sufficient to determine the speaker and major context; others might choose a smaller or larger range depending on their study goals and design). This procedure allowed 237 such instances (reporter remarks, interviewer questions) to be identified and excluded from further analysis. Thus, a total of 2,125 apologetic lexemes ultimately served as the basis for this analysis.

One person completed the content analysis. As a check of reliability, a second person coded a randomly selected subsample consisting of approximately 8% of the lexemes. Overall, chance-corrected rates of agreement (that is, taking into account the amount of agreement between multiple coders that could occur based on chance as opposed to deliberate agreement) ranged from 0.72 to 1.00 (see Cohen, 1960). Specifically, chance-corrected agreements were as follows: self-reference 0.82, tense 0.83, willingness 0.92, specifying the act 0.73, specifying the wrongdoer 0.72, and use of the apology lexeme 1.00.

Analysis

Research Question 1

RQ1 explores the extent to which modern presidents have used apologetic rhetoric in their public messages to foreign audiences. Apologetic rhetoric is indicated by the use of respective lexemes that reveal the act not only of apologizing, but also of regretting own behaviors and other events, admitting past mistakes, or asking for reconciliation. Figure 12.1 (based on $n = 2,125$) presents presidents’ *overall use* of these lexemes, controlled for total word count.

Figure 12.1 Apologetic rhetoric in presidential messages abroad, per 10,000 words ($n = 2,125$)

The findings suggest that modern presidents have remained fairly consistent in their overall use of apologetic rhetoric. They averaged 5.6 apologetic lexemes per 10,000 words, with Johnson (8.9), Eisenhower (7.6), and Roosevelt (6.8) scoring above that average, and Ford (3.4), Nixon (3.6), and Carter (5.1) scoring below average. While the biggest changes occurred in the 1960s and 1970s, the use of apologetic rhetoric has remained fairly constant since Reagan.

Although this initial analysis provides some preliminary insight into presidents' use of apologetic rhetoric *in general*, narrowing the parameters of this rhetoric provides a more precise look at presidential behavior. A major distinction can be made by separating self-referential remarks (e.g., "our mistakes") from other-referential utterances (e.g., "their fault"). In roughly 40% of all cases ($n = 843$) presidents referred to either themselves or the nation, as opposed to 60% where presidents applied any of the given lexemes to either refer to the injustices or mistakes of others, or to state general phrases without further specification of the source ($n = 1,282$). Specific examples of other-referential units are "The Taliban and Saddam holdouts are desperately trying to stop our progress; they will fail" (G. H. W. Bush, 1990) and "It's easy to point fingers and to pin the blame of these problems on others" (Obama, 2009).

Note that those instances were then separated from "minor" apologies and hypothetical statements. For example, presidents often apologize for arriving late at a scheduled speech occasion or departing early from the visited country, or presidents

say “sorry” or “excuse me” in press conferences when they do not understand the question. While this may be indicative of a speaker’s politeness, these instances are not meaningful in the context of apologetic rhetoric; 309 such minor remarks (36.7% of all self-referential instances) were identified and excluded from further analysis. Expressions of regret and sorrow in case of natural disasters (e.g., a country’s victims struck by a hurricane or an earthquake) or the death of a foreign leader ($n = 84$, 10%) were also excluded. Likewise, presidents apply another rhetorical strategy: the use of the conditional tense to describe potential, not actual, failures. Examples include “if we fail to act in the face of danger, the people of Iraq will continue to live in brutal submission” (G. W. Bush, 2002) or “our children and grandchildren will never forgive us *if* we allow new and unstable nuclear standoffs to develop around the world” (G. H. W. Bush, 1992). While these instances describe possible failures the United States could commit, they are nonetheless hypothetical situations and therefore not truly representative of apologetic rhetoric; 115 such phrases were excluded from the final analysis (13.6% of all self-referential remarks). Taken together, the result of these necessary exclusions is that a total of 333 units (only 15.7% of all mentions originally identified via CCA) exist that are truly representative of modern presidential apologetic rhetoric. These units serve as the basis for further analysis.³

The trend (see Figure 12.2) – looked at in this more nuanced fashion – reveals a decrease in apologetic rhetoric throughout the modern presidency. Two of the three early modern presidents have been most likely to apply apologetic rhetoric. Roosevelt averages 2.6 mentions per 10,000 words, followed by Eisenhower (2.0) and Reagan

Figure 12.2 Self-referential apologetic rhetoric in presidential messages abroad, per 10,000 words ($n = 335$)

(1.4). A first change occurred in the mid-1960s, determined by four consecutive presidents who were among the least likely to use such rhetoric: Johnson averages 0.6, Nixon 0.4, and Ford 0.2 mentions per 10,000 words. A second change took place with Reagan entering office. Apologetic rhetoric was somewhat revived and has since remained fairly consistent. Although both Bush presidencies account for slight downward trends, Obama appears to be more similar to Reagan and Clinton when it comes to the extent of using apologetic rhetoric abroad, averaging 1.1 mentions per 10,000 words. However, the more recent presidents clearly do not reach the levels of early modern presidents. Additional differences exist with regard to party affiliation. While Democrats average one apologetic instance per 10,000 words across all messages ($SD = 0.66^4$), Republicans average 0.76 instances per 10,000 words ($SD = 0.69$), thus suggesting that Democrats have been more likely to apply apologetic rhetoric. It is impossible to know for certain what caused the downward trend in the 1960s. One possibility, though, is that the general lack of media coverage and the absence of journalists abroad might have caused early modern presidents to employ such language more easily than succeeding presidents. With a general increase in media coverage, presidents may have become more cautious about their message content. This is consistent with the Cold War context: any self-critical statement made by the president could potentially be interpreted as a sign of weakness by the ideological opponent.

To answer RQ1, then, it can be said that apologetic rhetoric in presidential messages abroad did not increase when controlled for president's total word count. In fact, it has remained fairly stable since Reagan. However, as demonstrated, much of this apologetic rhetoric is barely apologetic by the standards set forth above. Thus an analysis using a more rigorous focus on apologetic rhetoric revealed that modern presidents have *decreasingly used such language when referring to the nation*. Democratic presidents have been more likely than Republican presidents to admit the nation's past mistakes and to express sorrow about them. Individual presidential differences become manifest when contrasting Roosevelt and Eisenhower, the presidents most likely to use apologetic rhetoric, with Nixon and Ford, who were least likely to do so.

Research Question 2

RQ2 focuses on specific terms in apologetic rhetoric that presidents have used in their public messages delivered to foreign audiences. Based on the mixed approach to content analysis utilized in this study, we found that the most frequently occurring lexeme turned out to be "reconciliation" ($n = 107$, or 32% of all units considered herein), followed by "mistake" ($n = 66$, 19.8%), "fail" ($n = 43$, 12.9%), "regret" ($n = 19$, 5.7%), and "error" ($n = 12$, 3.6%). The strongest indicator of apologetic rhetoric, the term "apology" including its derivatives, was mentioned *only 13 times* in all 2,186 public messages. Religiously connotated terms such as "forgiveness" ($n = 3$),

Table 12.1 Frequencies of self-referential apologetic lexemes
(*n* = 335)

	Lexemes	Frequency (%)
1	Reconciliation	107 (32.0)
2	Mistake, flaw, fault, error	94 (28.0)
3	Fail	43 (12.8)
4	Regret	19 (5.7)
5	Apology	13 (3.7)
6	Injustice	12 (3.6)
7	Blame	12 (3.4)
8	Sorrow	8 (2.3)
9	Excuse	7 (2.0)
10	Sin(s)	7 (2.0)
11	Guilt	5 (1.4)
12	Forgiveness	3 (0.9)
13	Shame	3 (0.9)
14	Confession	3 (0.9)
15	Amends	1 (0.3)
16	Deplore	1 (0.3)
17	Pardon	1 (0.3)
18	Plea	1 (0.3)
19	Atonement	0
20	Remorse	0
	Total	335 (100.0)

Note: *n* = 335 is based on self-referential apologetic lexemes reduced by minor remarks, hypothetical situations, and expressions of regret for external events (not caused by the United States or the US president).

“confession” (*n* = 3), “sin(s)” (*n* = 7) were barely used by presidents while others (“atonement,” “remorse”) were not used at all when referring to the United States. Table 12.1 summarizes these frequencies.

To answer RQ2, then, it can be noted that presidents have mostly framed their apologetic statements by referring to mistakes and reconciliation. Both account for more than half of all lexemes included in this analysis. One might argue that by using the word “mistake” (instead of a stronger term such as “injustice” or a clear acknowledgment of guilt or shame) presidents attempt to downplay a wrongful act’s significance. To further illustrate, consider two examples from the discourse: “The errors we made, or at least the political decisions we made, caused us problems” (Clinton, 1997) and “We are not saints, we know we make mistakes” (Eisenhower, 1960). With regard to “reconciliation,” one might argue that instead of addressing the nation’s past, presidents prefer to draw attention to the present and the future. Instead of focusing on the roots of a conflict, presidents have chosen to highlight reconciliation as the healing process or the outcome of that process. An additional analysis shows that it is more common for presidents to position the United States

as a mediator or an active promoter of reconciliation between others (“America is using its influence to foster peace and reconciliation in the Holy Land,” G. W. Bush, 2008) and less common to present the United States as a nation that needs to be reconciled with other nations (“Americans and Germans came together, reconciled, and united for freedom,” Reagan, 1985). The almost complete absence of the term “apology,” however, casts some doubt on the idea that the US presidency has entered an “age of apology.”

Research Question 3

RQ3 asked about the differences of apologetic rhetoric regarding the message format. Messengers can have varying levels of control over the message. While news conferences are considered low in message control, major addresses before a foreign parliament, a foreign public, or the UN General Assembly are typically crafted messages, scheduled ahead of time and therefore prepared with diligence, often with the support of professional speechwriters. The overall trend suggests that, for the most part, presidents are more likely to apply some form of apologetic rhetoric when they have higher message control (i.e., speeches to political entities or citizens). Figure 12.3 illustrates that trend.

Figure 12.3 Self-referential apologetic rhetoric and message type (low versus high message control) ($n = 333$)

In particular, in their news conferences abroad presidents averaged 0.7 apologetic mentions (per 10,000 words), as opposed to 1.0 such mentions in all other spoken and written remarks. Presidents highest in apologetic rhetoric in news conferences were Roosevelt (2.6), Eisenhower (1.4), Clinton (1.0), and Obama (0.9), whereas Truman, Kennedy, Johnson, Nixon, and Ford were lowest, with apologetic rhetoric being virtually absent from the discourse.⁵ Beginning with Carter, news conferences abroad became an essential part of modern presidential rhetoric. When presidents had more control over the message they were also more likely to use such rhetoric. However, the overall trend for those messages mainly follows the trend for messages low in control. Once again, two early modern presidents, Roosevelt (2.5 times per 10,000 words) and Eisenhower (2.0), and Reagan (1.6) were most likely to apply apologetic rhetoric in crafted speeches, as opposed to Ford (0.2), Nixon (0.4), and Johnson (0.6) who were the presidents least likely to do so. One might argue that this increase is due to reporters' behavior becoming increasingly "aggressive" in broaching the issue of past wrongdoings (e.g., a standard question asked by reporters is "What is your greatest regret of your presidency?"), thus urging the president to respond carefully. In an effort to avoid such questions, presidents might have adopted a rhetorical style and become more apologetic in their crafted speeches to pre-empt those attacks.

Research Question 4

The final research question focuses on the units that were found to be self-referential based on the discussion provided under RQ1 ($n = 333$). A first rhetorical strategy that has been discussed in the extant literature is the *willingness* to admit mistakes, to express sorrow and regret at past injustices, to apologize, or – more generally – to engage in self-criticism. In the following, we will refer to this as *self-critical* instances of apologetic rhetoric, thus excluding all mentions of reconciliation, refusals to apologize, and other defensive acts. For all further analyses we will also draw several comparisons by dividing the modern presidency along party lines (Democrats and Republicans) as well as in three broad phases (pre-Cold War, Cold War, and post-Cold War).⁶

Generally, it can be assumed that presidents who apply a more reconciliatory rhetoric demonstrate more willingness to admit past wrongs, whereas presidents who apply a more defensive rhetoric are less likely to do so. Presidents have admitted mistakes and acknowledged flaws to varying degrees: seven times in the early stages of the modern presidency (the pre-Cold War era), 68 times during Cold War, and 115 times in the post-Cold War phase. From a relative perspective, however, post-Cold War presidents have been slightly less willing than Cold War presidents to confess: during the Cold War presidents averaged 0.51 signals of willingness (per 10,000 words) while presidents governing in the 1990s and 2000s averaged 0.48 such signals.⁷

Figure 12.4 Self-referential ($n = 335$) and self-critical instances ($n = 191$) of apologetic rhetoric in presidential messages abroad

The distinction between self-referential units (those rhetorical moments where presidents broadly refer to themselves and the nation as opposed to others) and – being a subsection of it – self-critical units (those where presidents publicly made some form of criticism of the nation, for example, by admitting mistakes) is illustrated in Figure 12.4. The dashed gray line represents all self-referential units ($n = 333$, congruent with the line in Figure 12.2; note that this also includes few cases where presidents refuse to apologize or deny that mistakes happened), while the solid line marks all self-critical units ($n = 190$; both per 10,000 words). Additionally, given the prevalence of the reconciliation lexeme among all self-referential units, a third (dashed black) line is shown that refers to all self-referential units excluding all mentions of reconciliation ($n = 226$). The previously observed party differences remain when focusing on just the self-critical instances of apologetic rhetoric ($n = 190$). In particular, Democrats averaged 0.6 public confessions per 10,000 words ($SD = 0.57$) whereas Republicans averaged 0.4 public confessions per 10,000 words ($SD = 0.53$).

Recall that one of the major conclusions of RQ1 was a downward trend that began in the 1950s and reached its low point in the mid-1970s, followed by an upward trend in the 1980s that has since remained fairly consistent. This trend is represented by the gray dashed line in Figure 12.4. It is apparent that the increased usage of the term “reconciliation” (especially by Reagan, Clinton, Johnson, and Eisenhower) is responsible for some of the variation, as indicated by the gaps between the two dashed lines in Figure 12.4. Excluding reconciliation from this trend thus results in a more flattened curve in the recent past. This in turn strongly follows the trend line resembling only the self-critical instances. When focusing on those specific instances the tendency for most modern presidents to admit mistakes is not entirely different from the observation made under RQ1. However, the differences between post-Cold War presidents are now more pronounced, particularly when comparing Obama to his predecessors. While G. H. W. Bush, Clinton, and G. W. Bush rather resemble Reagan, there was an upsurge in 2009 when it came to presidential criticism of the United States (its previous administration, in particular).⁸ This in turn is more reminiscent of the early days of the modern presidency.

A second rhetorical strategy is to focus on the *type of wrongdoing*, particularly the degree of specificity with which modern presidents have admitted past mistakes and injustices. In the past, presidents have acknowledged specific wrongdoings and historical injustices, ranging from slavery and segregation to support of corrupt regimes and military dictatorships, and policy failures regarding energy, immigration, or foreign affairs. In so doing, presidents may be more specific (e.g., “it’s one of my great regrets that it did take so long in Bosnia” (Clinton, 1999)) or less specific (“whatever mistakes we have made” (Obama, 2009)) in acknowledging wrongdoings. In general, modern presidents have been willing to admit specific mistakes in nearly two-thirds ($n = 120$) of the cases in which mistakes were admitted; one-third relates to rather general phrases and superficial remarks ($n = 70$). In particular, presidents more likely to specify their own or the nation’s mistakes were Kennedy and Johnson (both 100%), G. W. Bush (80.8%), and G. H. W. Bush (73.3% of all mistakes acknowledged were specific). Presidents less likely to specify their own or the nation’s mistakes were Eisenhower (68.8% of all mistakes acknowledged were rather general confessions), Reagan (50.0%), and Obama (50.0%). On average, presidents governing in the post-Cold War era were *slightly more likely* to specify their mistakes (67.8%, $n = 78$) than their predecessors (55.9%, $n = 38$) in cases where those were admitted. However, when controlled for number of words, those differences disappear: Whereas Cold War presidents admitted 0.29 specific mistakes on average (per 10,000 words), post-Cold War presidents admitted 0.32 specific mistakes.⁹ Interestingly, although post-Cold War presidents have been *slightly less willing* than Cold War presidents to confess, they have been *slightly more specific* than Cold War presidents in acknowledging mistakes, thus indicating a more reconciliatory, less defensive rhetoric prevalent in the 1990s and 2000s.

A third rhetorical strategy is to focus on the *identity of the wrongdoer*, particularly the degree of specificity with which modern presidents reveal their own or their

nation's role in committing mistakes. Previous research suggested that omitting, concealing, or de-emphasizing certain information (such as the wrongdoer's identity) may be one form of reducing responsibility (Fairclough, 2000; Kampf, 2009a). To do this, presidents might use the personal pronoun "we" without explicitly linking the transgression to the United States. For example, presidents may refer to a failure committed by a broader alliance of nations including the United States (e.g., G. W. Bush's "Coalition of the Willing"; the UN in its entirety; or simply the West), as in "the failure of the *Allied nations* to make more progress in *their* common search for a lasting peace" (Truman, 1946) or "inescapable human errors in *our* long record" (Eisenhower, 1956). Post-Cold War presidents were less likely (56.5%, $n = 65$) to use such general forms than their predecessors (72.1%, $n = 49$) in cases where mistakes were acknowledged during that period. In fact, post-Cold War presidents were *more likely to engage in self-criticism emphasizing the United States* (26.1%, $n = 30$) than their predecessors (17.6%, $n = 12$), as illustrated, for example, in "There's plenty of blame to go around for what has happened, and *the United States* certainly shares its blame for what has happened" (Obama, 2009) or "perhaps the worst sin *America* ever committed about Africa was the sin of neglect and ignorance" (Clinton, 1998). Similarly, Clinton, G. W. Bush and Obama were also more likely than their predecessors to admit personal mistakes (16.5%, $n = 19$ versus 10.3%, $n = 7$), such as "I've already said *I* made a bad mistake, it was indefensible" (Clinton, 1998). Compared with Cold War presidents, the four presidents governing in the 1990s and 2000s have been slightly less likely to signal willingness to admit past mistakes and express regret, but slightly more likely to engage in self-criticism highlighting themselves or the United States as the principal wrongdoer and clarifying the nature of the transgression.

Nonetheless, modern presidents have primarily avoided highlighting the United States as a principal wrongdoer, and instead made generalizations about the offending parties by not outlining and further specifying the role of the United States in previous conflicts and wrongful acts. Presidents seem to reduce responsibility and "democratize" blame by applying certain rhetorical strategies that are used to blur the identity of the offender, or distort the nature and dimension of the act itself.

Conclusion: Advantages and Disadvantages of a Mixed Approach

This chapter aimed to illustrate the process of a mixed approach to content analysis through a study of modern American presidents' apologetic rhetoric. The study presented here has, we hope, demonstrated the many advantages of this approach. We briefly reflect on these advantages below, and also highlight some of the disadvantages of adopting this method.

The mixed approach shares one of CCA's greatest strengths: the ability to process large quantities of data. Rather than having to rely on a sample of relevant moments,

the mixed approach allows scholars to speak with authority about over-time trends in the census of relevant text. In the case of presidential apologies abroad, for instance, we can be more certain of our generalizations than we would be if we were manually coding a smaller sample of texts, or if we had limited ourselves to fewer lexemes. The use of the automated procedures discussed above made such certainty possible. Just as clear, however, is that had we only relied on these automated processes, our ability to fully understand presidents' apologetic rhetoric would have been severely constrained. Additional manual coding provided a much more nuanced view of the data. In this case, at least, neither of the two methods would have been sufficient by itself: while manual coding of more than 2,000 documents would not have been manageable given pragmatic considerations, relying on CCA alone would have generated very different findings – and provided even misleading trends. For example, recall that our data showed a considerable number of “minor apologies” and hypothetical statements. These common speech elements are not truly representative of apologetic rhetoric, but would nonetheless have been captured by the computer. Without manual coding to eliminate such instances, the data would have been far less accurate and useful.

The possibility of narrowing the search results down to a limited number of relevant texts (while excluding irrelevant entities) also facilitates the search for qualitative evidence that can help provide greater meaning to quantitative trends. This can be useful to substantiate findings when interpreting or explaining the results of a study, for example, by facilitating the process of finding illustrative quotes in the texts. Simply put, instead of wading through a sea of text, the content analysis software generates a compressed file of relevant utterances (using concordances) from which the researcher can easily choose. This feature also allows the researcher to double check data for negated statements and ambiguous remarks – elements that can mask crucial bits of data if not identified. The mixed approach thus allows rhetorical trends to be interpreted more accurately than they might otherwise be, and is therefore especially useful for many diachronic research endeavors.

Researchers adopting this approach should also be aware of a few disadvantages. Central among these is that a mixed approach is more time-consuming than traditional CCA, given that it adds the manual component. But it is also worth knowing that even the automated components are not possible without considerable time spent preparing the files for the computer. For instance, creating a text file with all sample documents and “data cleaning” may sometimes be necessary to make the actual analysis more manageable and meaningful. Setting up a dictionary of key terms can be a time-consuming endeavor too, but it is essential to make the initial term search as exhaustive as possible. Some studies (e.g., Coe, 2011) generate the dictionary of search terms directly from a complete list of every distinct word used in the corpus of texts. This approach is the surest means of making the dictionaries valid but is also extremely time-consuming.

Additionally, there will always be in the mixed approach some degree to which the manual coding is limited by lack of context. For example, a traditional content

analysis of presidential speeches would have human coders reading entire speeches and coding for certain categories as they appear in the texts. In contrast, the mixed approach isolates key terms and has human coders code those terms within some limited amount of contextual material (e.g., 150 characters on either side of the term, our chosen amount of context in the present study). Coding decisions made by humans who have read an entire speech have the potential to be more sophisticated than those made by humans who have read only a small passage. In nearly all cases, however, this limitation of the mixed approach can be compensated for by carefully selecting the categories that will be central to the analysis. It is simple, for example, to understand from just a small amount of context whether a president is apologizing for his own actions or for those of others. Thus the mixed approach is effective in this case. If the coding categories require judgments that are quite complicated, however, the mixed approach is probably less useful than traditional manual coding.

Obviously, our focus has been on just one narrow context: modern presidents' apologetic rhetoric. But the mixed approach has broad applicability to various other contexts. For example, future studies might focus on the corporate level where apologetic rhetoric is used as a means of image repair, especially when relations between a company and its customers have been strained due to an environmental, safety, or health crisis. Numerous case studies have been conducted (e.g., Benoit & Lindsey, 1987; Hearit, 1994) but a quantitative assessment has been largely absent from the literature. A mixed approach could thus be used to examine companies' crisis response messages over time or by sector. Similarly, given that political discourse happens in interaction between political elites, the public, and the media, the mixed approach can also be used to incorporate citizen blogs or news media content. In so doing, one can analyze how particular moments of presidential apologetic rhetoric are perceived and interpreted by citizens or reported and commented on by the (international) news media. Such studies, for example, may focus on a single presidency but allow for a number of media responses (to presidents' apologetic rhetoric) to be included. Scholars can thus gain additional insight into which media outlets turn a particular moment of apologetic rhetoric (as the forms identified herein) into an "apology" *per se*, which would perhaps explain much of the recent discussion about the "age of apology" (Gibney et al., 2008; Kampf, 2009b).

More broadly, the methodology outlined in this chapter can be applied to analyze discourse beyond topics related to political communication and can be conducted in every language (assuming the content analysis software is able to process non-English language or non-roman letters). The mixed approach to content analysis employed and explained herein is suitable for scholars interested in processing large quantities of text (to examine broader rhetorical trends) yet do not want to refrain from taking a closer look at rhetorical nuances. Research might focus on such areas as environmental communication (e.g., framing of climate change in news coverage), health communication (e.g., examining arguments used in public health messages), or mass communication (e.g., portrayal of minorities and use of stereotypes in mass

media). Whatever the context, the mixed approach should give scholars a useful tool for better understanding various forms of spoken and written communication.

NOTES

- 1 Texts of presidential speeches, from which all quotations and analyses are drawn, were retrieved from the *American Presidency Project* (University of California, Santa Barbara, n.d.).
- 2 For further information see www.textquest.de.
- 3 Although those other-referential units constitute apologetic rhetoric to a great extent, they were not part of further analysis. That presidents have been more likely to refer to the mistakes and faults of others is nonetheless interesting, but in order to give an accurate account of presidential apologetic rhetoric, only self-referential remarks are included in further analyses.
- 4 *SD* = standard deviation.
- 5 It should also be noted that those five presidents held very few press conferences abroad compared to all other modern presidents.
- 6 For this study, the pre-Cold War era was defined as Franklin Roosevelt's inauguration (March 4, 1933) through the end of World War II (specifically the Pacific War on September 2, 1945). That was followed by the Cold War era, which lasted until the dissolution of the Soviet Union on December 25, 1991. The post-Cold War era then continued to the present.
- 7 World War II presidents Roosevelt and Truman averaged 1.55 apologetic lexemes per 10,000 words, thus confirming previous trends suggested earlier.
- 8 However, caution is recommended in judging the rhetorical trend President Obama has set in his first 15 months in office. Presidents have generally traveled abroad more during their first year in office than in the years afterwards. In the case of Obama, for example, roughly half of the country visits made during his first term were in his first year in office (25 out of 51). Hence, it remains to be seen if the rhetorical signals Obama sends in his second term are compatible with his first year's rhetoric.
- 9 World War II presidents Roosevelt and Truman fall somewhere in between (57.1% of all mistakes acknowledged were specific, $n = 4$) and averaged 0.89 specific mistakes per 10,000 words.

Lessons Learned from a Research Saga

An Ambitious Content Analysis of Television Form

Matthew Lombard

ABSTRACT

A team of researchers led by the author developed, designed, conducted, and reported a large-scale content analysis of the structural features of television. The project was unusually ambitious and, by necessity, creative. The chapter describes some of the key decisions and challenges the team faced along the way and the unexpected afterlife of the original project. The author concludes with advice for content analysis and for other researchers based on lessons learned from the experience.

This chapter describes lessons I learned from a long research saga: designing, conducting, writing up, presenting, and publishing an ambitious content analysis of television form and its unexpected offshoot projects. The origins of the research project are described first. This is followed by a discussion of some key issues and challenges the research group faced regarding the design. These include issues with sampling and material collection, the development of measures, coder selection and training, inter-coder reliability, data entry and analysis, and writing, authorship, and presentation of the original study. The chapter also discusses the project's unexpected afterlife. It

concludes with advice based on lessons I learned about conducting not just content analyses but any research project.

Origins: Developing Research Questions

The saga began in early 1995, when I was a junior professor in the Radio–Television–Film department at Temple University. Although research questions and hypotheses can come from personal observations, “future research” sections of published articles, and a myriad of other places, the questions in this case arose naturally from my previous work. My dissertation project at Stanford University, and a subsequent series of three experiments conducted with a group of doctoral and master’s students at Temple, had explored “direct responses” to mediated stimuli – what I would later identify as presence (short for telepresence). The idea was that, at least in some cases and to some degree, people respond to images and sounds on television (and in other media) not as representations of people, objects, and events but as the people, objects, and events themselves (i.e., directly). The first experiments used created and then found footage of individual people speaking to a camera. They manipulated screen size, shot length, and viewing distance (independent variables) to replicate the dynamics of “personal space,” demonstrating that when people are made to feel physically close to people on the screen, their responses (dependent variables) mimic those in nonmediated settings (see Lombard, 1995). The Temple studies (Grabe, Lombard, Reich, Bracken, & Ditton, 1999; Lombard, Ditton, Grabe, & Reich, 1997; Lombard, Reich, Grabe, Bracken, & Ditton, 2000) expanded the types of content tested and established that the formal production feature we called quick, forward point-of-view movement – as when a camera is attached to the front of a roller coaster or race car – produces a greater sense of enjoyable physical self-motion (measured via questionnaires) and physiological arousal (measured via finger sensors that capture the skin’s electrical conductivity) when the filmed movement is viewed on a larger screen, an indication that viewers felt more “present” in the scenes.

These studies demonstrated that we could produce presence responses in viewers in an experimental setting, but they led us to wonder how often media consumers in the “real world” actually have these responses. We wanted to know how often, when, on which kinds of programs and channels/networks, and especially in which ways the presentation characteristics of television were most likely to evoke a sense of presence in viewers. We realized this would be an ambitious, time-consuming research project, and wanting to be efficient, we brainstormed about other ways we could use the data we would collect. Since most of the variables we had measured would concern the form rather than the content of television, and since there was already an extensive literature in media psychology regarding how viewers respond to many of these “formal features” (see Lombard, Bracken, Linder, Snyder, Ditton, Kaynak, Pemrick, & Steward, 1996), we would be able to assess and report on the

“state of the medium” at the time, allowing researchers to extrapolate about viewers’ responses to everyday viewing. We and others had noted the apparent increase in TV clutter – more, shorter commercials and promotional messages in more and longer program interruptions, and more complicated and potentially distracting graphics in news programs – so another part of our research could provide empirical evidence regarding these contributors to clutter. And we dreamed of future studies that would examine television in different eras as well as other media, expanding our Structural Features (SF) projects, conveniently abbreviated SF-Presence, SF-State, and SF-Clutter, into a near endless series of future projects.

Design

While it is possible – and some might say common – to choose a method first and to adjust one’s research questions to fit it, the best approach is to identify the questions first and select the most appropriate method(s) to address them. In this case, content analysis – “a research technique for the objective, systematic, and quantitative description of manifest content of communications” (Berelson, 1952, p. 74) – was the obvious choice. Although I had never conducted one, I had learned about the method and read many reports of content analyses. I knew the coding itself, which involves categorizing the content into meaningful categories, would be monotonous (in graduate school we were told every researcher should do the coding on one project and then have other people do that work in future projects!). But after conducting experiments and surveys I particularly liked the idea that a content analysis would not require us to recruit and deal with the quirks of human participants or even to obtain approval from an institutional review board (IRB) to conduct the study. So we set about designing the ambitious content analysis, which meant making careful decisions about what material to collect and code, what characteristics (variables) to measure, how many coders we would need and how to train them, how to evaluate the consistency or agreement of the coders (intercoder reliability), and how to record, analyze, and summarize the results.

Sampling and Material Collection

Because we were setting out to study not a specific genre (e.g., news), content feature (e.g., violence), day part (e.g., prime time), type of channel (e.g., major broadcast networks) or formal feature but all of television, we chose to sample the 10 broadcast stations in Philadelphia (the fourth largest media market in the United States then and at the time of writing) and the 15 basic cable networks available in most households in the United States (according to *Cable TV*, April 30, 1995). The selection of most *available* rather than most *watched* cable networks was particularly

strategic because we wanted to include both the frenetic features of popular MTV and the sedate features of the less popular C-SPAN.

The standard and most available video recording medium at the time was VHS videotape – unfortunately not even as high in quality as the then already disappearing Betamax format. While the format allowed for six hours of recording at the slowest speed (EP), the analog video editing equipment we knew we would need to use for the coding could only display tapes recorded at the standard two-hours-per-tape speed (SP). We knew that the ideal sample would be compiled over a whole year of the traditional fall to spring TV season since there are likely seasonal variations in the form of television. To be practical and still capture some of this variation, we selected a four-week period that included weeks both during and outside of the spring ratings “sweeps” period, when stations select programming to maximize their audience for the more detailed ratings taken by ACNielsen.

We wanted enough material to compare channels and times of day, so we settled on recording six tapes for each of the 25 channels for a total of 150 tapes. We investigated the possibility of buying tapes from a bulk seller but ended up finding good deals at local electronic and department stores. We used the Minitab software to generate several different series of random numbers to select channels (1–25), weeks (1–4), hours (1–12), and a.m. or p.m. (1–12). We used the random numbers to create the list of dates, start times, and channels for the recordings, and refined the list by applying a “rule” that the selected times be three hours apart to prevent overlap and to insure that all day parts were represented. Then we divided the selected recording obligations among the six team members with access to VCRs, avoiding assignments that required the same person to record different channels at the same time. What we had not considered is that in some cases people would forget to program their VCR or misprogram it, that some machines and tapes would fail, and that during some of the selected recording times the channel would be off the air (although all but unheard of today, this was common then and a particular problem with a small local PBS station in our sample).

We dealt with these problems by using the random numbers to select additional recording details and ended up extending the sampling period to a fifth week (and seven rather than six recordings per channel). Between August 13 and October 13, 1995, 175 two-hour blocks of television broadcasts/cablecasts were recorded; 160 of the tapes (320 hours) of television programming were viable for coding. Even these many years later I have boxes in my office filled with the VHS tapes we created.

Measures

No one had conducted a study like this before. Most of the structural features of the television medium either had not been examined in research or, when studied (usually in regard to their effects), had been defined inconsistently or imprecisely. So we began with variables and definitions in a well-known production handbook (Zettl, 1984),

studies that examined particular structural features in any context, and our own knowledge of television production techniques. We quickly realized we could not even have a useful conversation without developing a lexicon of basic terms; for example, a *frame* is an individual photograph on a videotape, the *screen* is the physical border that encloses the image on a television set, an *image* refers to the contents of the entire viewing screen, and a *picture* is a self-contained, bordered representation of objects and entities (there may be more than one picture in a given image).

To create our coding instrument we identified as many formal features related to presence, psychological processing research, and various types of video clutter as we could find or create. The variables represented characteristics of television form at several distinct levels including a single frame (e.g., camera shot length), a continuous shot (e.g., shot duration), a transition between shots (e.g., type of transition – cut, dissolve, etc.), a 10-second interval (e.g., artificial special visual effects), a program segment (e.g., genre), and an entire program (e.g., duration of opening and closing credits). In many long discussions we eliminated variables that were similar to each other or relatively unimportant, or that we decided we could not code reliably. Then we assembled two rough and incomplete coding manuals – one for complete programs and one for variables linked to single “time points” – that contained each variable and its corresponding response options, detailed definitions of terms that we thought might not be understood by different people in the same way, and examples to illustrate what we considered proper coding of many of the variables. We used extra tapes we had recorded to discuss each of the variables and how we might refine our collective understanding and the corresponding written descriptions of each one. Along with detailed instructions for coders, the final version of the “Coding Manual for Program Variables” was 23 pages long and contained 11 variables (in addition to several that identified the details of the recording and coder). The “Manual” for time point and 10 second interval variables was 39 pages long and contained 27 variables.¹

The 320 hours of recordings contained 322 complete programs. We used Minitab again to randomly select seven time points (hours, minutes, seconds) for each codable two-hour recording, resulting in what was eventually a total of 965 codable time points. The time points were restricted to being five minutes apart to reduce the likelihood of repeated coding of the same parts of the recording. These time points determined the units to be coded for a single frame (the image at the time point), a shot (in progress including the time point), a transition (the first that followed the time point), a 10 second interval (beginning with the time point) and a program segment (in progress at the time point).

Coder Selection and Training

Because our sample of television recordings was so large and our coding scheme so extensive, we decided we needed to hire additional coders to share the work. Even

with optimistic estimates of the time required to code a single program (15 minutes per program, 25 minutes per time point), and with the need for additional coding to establish that we could code reliably, we had set a huge task for ourselves. While some members of the research group were students being compensated for their time with assistantship awards, course credit, research experience, and/or authorship (more on that below), we needed more hands. Using a small research grant I had received from Temple University, we hired three people – one doctoral student and two undergraduates who answered an open call for those who might be interested – and signed contracts outlining an agreement to pay them each \$1,000 in return for their completing training and then performing both reliability assessment coding and regular coding. Given the unpredictability regarding complications and time commitments along the way, we made the payment contingent on completion rather than based on an hourly rate. Extended conversations with each of the paid coders confirmed their basic understanding of the coding process and the required focus on detail, sense of commitment and responsibility, and overall reasonableness, an especially important criterion.

We began the coder training process by having everyone read the detailed coding manuals we had created and report any questions or problems. The coders then coded just one and then a series of programs and time points from a set of recordings that was not part of the study sample but made at the same time. At each step, we responded to issues that came up and in many cases altered the coding instrument and manual accordingly. For example, several variables were dropped because of concerns about reliability (as will be discussed shortly). The process took several sessions over a period of weeks.

Intercoder Reliability

I knew from graduate school and from reading reports of content analysis that an essential component of the method is the calculation of agreement among coders, which establishes that the patterns reported are not those perceived idiosyncratically by a single researcher but are matched by those of other independent observers. However, I naively assumed that researchers had long ago reached consensus on the best index of this inter-judge agreement, made available software tools to conveniently calculate reliability values, and established standard criteria for evaluating the values. We soon realized none of this was true and began searching for authoritative guidance on how to proceed.

We learned that merely calculating the percentage of times coders did agree out of all the opportunities they had to do so – though intuitive, easy, and commonly reported (Pasadeos, Huhman, Standley, & Wilson, 1995) – overestimates coder reliability. For example, two coders randomly selecting the values of a two-category variable would agree 50% of the time (see Seun & Lee, 1985). Of the other indices,

Cohen's kappa and Scott's pi seemed to be the most common and recommended, but the former was also criticized as inappropriate and both had significant limitations given our data set (as many as seven coders, all levels of measurement from nominal (e.g., yes/no) to ratio (e.g., durations)). Krippendorff's alpha seemed generally accepted and flexible, but extremely complex to calculate especially given our large number of variables. Thankfully, Professor Krippendorff worked across town at the University of Pennsylvania and generously allowed us to use a beta version of a software program he had commissioned. It was a bit primitive and required (as most reliability software does) a very specific arrangement of the input data, but it was a lot more practical than the alternatives – "by hand" calculations or custom-designed programs known as macros we created for use with SPSS analysis software.

Because we set out to code the manifest rather than latent or hidden characteristics of television, we expected it to be relatively easy to get coders to consistently make the same choices among the response options for each variable as they watched the recordings we had made. But our first test of coder reliability was a miserable failure. We quickly identified a primary reason: We hadn't realized that in the era of analog recordings on magnetic tape, which stretches and slips with each play, there is little chance of two people finding the exact same frame (time point) on a tape. So before we could demonstrate similar decision processes, we had to insure we were making decisions about the same things. After some brainstorming, we solved this problem with something we called an "anchor frame." The first person to code a recording moved the tape to the previously selected random time point frame, set the time counter to 00:00:00:00, wrote down a short description of the image at that frame, moved the tape forward to the first frame that followed the first cut (not dissolve or other gradual transition) after the time point frame, and wrote down a description of the image at this "anchor frame" and how many frames it was beyond the time point frame. Each subsequent coder then used the descriptions of the time point and anchor frames and the distance between them to insure they were about to complete the coding sheet based on the identical starting time point.

With the mundane mechanical obstacles to reliability removed, we were surprised to find that the coders were still making different judgments regarding many of the variables. The reasons were predictable – vague definitions and descriptions, unforeseen characteristics in the recordings – but frustrating. It turned out that television form is much more complicated and subtle and less manifestly obvious than we had initially thought. One coder who had rarely watched television helped the rest of us identify large and small assumptions we had made about how to understand and categorize what we were coding.

One example of the kinds of refinements to the coding instrument and manual that these reliability problems led to stands out, and also illustrates the type of information we had to provide for the coders to insure reliable results. In the early versions of the coding manual a variable meant to assess a type of presence was "Apparent broadcast type" at the beginning of each 10-second interval to be coded. It appeared in the manual this way:

30. Apparent broadcast type?

- _____ Live in real time
- _____ Live on tape
- _____ Taped/Filmed

FULL QUESTION:

Which broadcast type does the image SEEM to be?

DEFINITIONS & EXAMPLES:

Apparent broadcast type – the broadcast type that a program seems to use. For example, a talk show often seems to be “live,” happening as it is presented to us.

Live in real time – events on screen seem to be actually occurring at the time you see them.

Live on tape – events seem to have occurred in the exact sequence in which they’re presented but at an earlier time; the video tape of those events is being played.

Taped/Filmed – events seem to have occurred in a different sequence from the sequence in the presentation and at an earlier time; the content is “constructed” through editing techniques (as opposed to techniques – such as computer graphics – that can be imposed onto content that is broadcast live in real time).

NOTES:

- If the broadcast type changes during the interval, code only the first type.
- Do not consider any knowledge you have about the actual broadcast type (e.g., “I know it’s a sitcom and that they tape those before they broadcast them”) – consider only the indications of broadcast type in the interval being coded.
- Note that you are coding a videotape of an actual broadcast – code this item as if you were watching the original broadcast.
- A cut alone does not provide sufficient reason to claim that the broadcast type is constructed (i.e., taped/filmed).

During practice coding and initial reliability testing it became clear that the variable was drawing coders to apply “facts not in evidence” (e.g., the timing and production attributes of an initial broadcast) and the only way to reach an acceptable level of reliability was to reframe the question in more direct and obvious terms. The entry in the coding manual was revised.

15. Indication of broadcast type?

- _____ [1] Text or sound include word “Live” (but not “Recorded Live”)
- _____ [2] Text or sound include a time and either day or date that DOES match the time and either day or date the tape was recorded
- _____ [3] Text or sound include word “Recorded”
- _____ [4] Text or sound include a day or date or time that DOESN’T match the day or date or time the tape was recorded
- _____ [0] NEITHER 1, 2, 3, or 4

FULL QUESTION:

During the 10 second interval is there any indication in picture or sound of the broadcast type, and if so, what is the first such indication?

DEFINITIONS & EXAMPLES:

Broadcast type – television programs can take events that occur in nonmediated reality and present them as the events occur, they can be recorded as the events occurred and then broadcast later, or they can be recorded in individual segments and constructed for broadcast later.

Text or sound include word “Live” (but not “Recorded Live”) – Either text in the picture or the sound during the 10 second interval, or both, contains the word “Live” and thereby indicates that the broadcast type is “events being presented as they occur.” Do NOT include “Recorded Live” in this category.

Text or sound include a time and either day or date that DOES match the time and either day or date the tape was recorded – Either text in the picture or the sound during the 10 second interval, or both, contain the time AND either the day (“Tuesday”) or the date (“July 5”), or both, that correspond with the time, AND day and/or date, the tape being coded was recorded, and thereby indicate to viewers that the broadcast type is “live” (e.g., during news programs and on the Weather Channel this information is often provided in one corner of the screen). Note that the day or date or both of them are not enough – the time of day must also be included.

Text or sound include word “Recorded” – Either text in the picture or the sound during the 10 second interval, or both, contains the word “Recorded” and thereby indicates that the broadcast type is “recorded as the events occurred and then broadcast later.” Include “Recorded Live,” “Recorded Earlier,” “Recorded in front of a live studio audience,” “Recorded for presentation in this time zone,” and similar messages in this category.

Text or sound include a day or date or time that doesn’t match the day or date or time the tape was recorded – Either text in the picture or the sound during the 10 second interval, or both, contain a day, date, or time (or any combination of them) that do not correspond with the day, date, or time the tape being coded was recorded and thereby indicate to viewers that the broadcast type is either “recorded as the events occurred and then broadcast later” or “events recorded in individual segments and constructed for broadcast later.”

NOTES:

- If the broadcast type changes during the interval, code only the first type.
- Do not consider any knowledge you have about the actual broadcast type (e.g., “I know it’s a sitcom and that they tape those before they broadcast them”) – consider only the indications of broadcast type in the interval being coded.
- Do not use any knowledge you obtain from content before the interval begins to code this item.

A more vexing problem regarding reliability concerned variables with little variation. For example, one variable required coders to indicate whether the images in a

10 second interval were color and/or black and white. Black and white images were exceedingly rare, in reality and in the coding results, but Krippendorff's alpha for the variable was near 0. If a single coder missed one of the rare instances of black and white, the formula determined that we could not reliably identify such occurrences and penalized us accordingly. Because we knew from our coding experience (and collective years of television viewing) that black and white content was so rare, we decided not to create and retest reliability with a new artificial sample of recordings that contained many black and white segments and instead established a rule that if Krippendorff's alpha was below a certain threshold (.7), percent agreement must be exceedingly high (.9). While reviewers might criticize this approach, we believed we could defend it as appropriate in the context of our variables.

Data Entry and Analysis

In an era of analog videotape, few laptop computers, and no iPads or other tablets, we had to make many printed copies of the coding sheets for the coders to complete with pen or pencil as they watched each recording. Coders then entered the data from the completed sheet by working in pairs, one person reading responses out loud as the other typed the information into a word-processing file on a desktop computer. Each coding sheet page generated a separate line of numbers in the data file. To identify the many possible errors from this data entry process, we printed each record entered and held the paper up in front of a bright light against another paper, a template of correctly entered data, to identify missing and extra characters and lines of data. Then all of the word-processing formatted files had to be converted to unformatted text files and combined as input data files for the then typically used mainframe version of SPSS, in which specific "jobs" had to be submitted and printed results picked up from numbered bins at a computer center on campus. A detailed data cleaning process followed, in which the frequencies of each response for every variable were calculated, unlikely or impossible values in the results checked, and errors in the data files fixed.

After all the very monotonous and time-consuming data entry and cleaning (first for reliability data and then the full program and time point data sets), the calculation of frequencies and cross-tabulations of frequencies for all of the variables was relatively simple and quick. While this is not the place for detailed reporting of the results, we were pleased that findings for approximately 70% of the variables related to presence suggested that viewing television encourages rather than discourages presence responses. For example, most television in the summer of 1995 was mostly color, live-action, with convergent sound and picture except for background music, leisurely paced with simple transitions, and very rarely included explicit on-screen indications that the material had been created earlier.

Writing, Authorship, and Presentation

Over the next four years (1996–1999) we reported the results of our research in peer-reviewed papers at the annual conferences of the International Communication Association (ICA) in Chicago, Montreal, Jerusalem, and San Francisco. Ironically the first two papers were focused on *The State of the Medium* (Lombard et al., 1996) and *The Cluttering of Television* (Lombard, Snyder, Bracken, Kaynak, Pemrick, Linder, & Ditton, 1997), with the third paper finally focusing on our original proposed study, *Presence and the Structural Features of Television* (Ditton, Lombard, Bracken, Snyder, Pemrick, Linder, & Kaynak, 1998). The fourth paper (Lombard, Snyder-Duch, Bracken, Ditton, Kaynak, Linder-Radosh, & Pemrick, 1999) reviewed the major findings in the entire project. With the exception of a student who moved away and left the project, the authors were the same for each paper but the authorship order was rotated according to earlier arrangements – fortunately, I had learned that such issues need to be negotiated early in the process to prevent disagreements and bad feelings later on.

While everyone including me had learned a lot, after five years and more time-consuming challenging obstacles than any of us had expected, the doctoral students on the research team became very busy in their new jobs as assistant professors, and in one case in industry, and we all gravitated to new projects. By the time we were able to revise the *State of the Medium* paper for submission to a journal in 2002, the recordings we had made were seven years old and perceived as out of date. It takes a team to bring a project to the final publication stage, but the team leader is ultimately responsible and I very much regret not doing more to follow it through. A respected senior scholar at one of the ICA conferences praised the project and suggested that pursuing it might become the primary focus of my academic career, with regular follow-up studies and explorations of new structural features in new media, but that was not to be. However, the project was far from over.

Unexpected Afterlife

Because we felt we had learned so much while designing, conducting, and reporting the study, the three people who had been most involved with it wrote and presented another conference paper that relayed some of what we had learned as a “guidebook” for those conducting similar large-scale content analyses (Snyder-Duch, Lombard, & Bracken, 1999).

The biggest unexpected challenges we had faced concerned properly assessing and reporting intercoder reliability. As we read other reports of content analysis studies in communication, we realized that many of them failed to adequately address – and

in some cases failed even to mention – this critical aspect of the method which is arguably most identified with our field. So, based on the annoyance generated by the fact that we had struggled to “do it right” while others had not, and as a service to others who might want to but did not know how, we began another project: a content analysis of intercoder reliability in communication content analyses – we called it CAR for “content analysis reliability.” The much simpler coding scheme, applied to a sample of 200 studies published between 1994 and 1998 and identified as content analyses in *Communication Abstracts*, confirmed that authors often (about 30% of the time) failed to report reliability. When they did report it they often (apparently, since the reports are typically vague) relied on the inadequate percent agreement index. Based on a review of concepts, indices, and tools, and our results, we provided a set of concrete guidelines to help other researchers to more easily and completely assess and report reliability.

Coincidentally, following our presentation of the CAR paper at ICA’s 2001 conference in Washington, DC (Lombard, Snyder-Duch, & Bracken, 2001), I saw a call for papers for a special issue of *Human Communication Research* on “Statistical and Methodological Issues in Communication Research.” We submitted the paper and it was quickly accepted. When the article (Lombard, Snyder-Duch, & Bracken, 2002) appeared, Professor Krippendorff contacted us to point out a handful of errors in a table that none of the three of us, or any of the reviewers or editors along the way, had noticed – a disconcerting commentary on the peer review process and a reminder to always review others’ and one’s own work carefully. Professor Krippendorff also lobbied us, in an increasingly unpleasant series of exchanges, to modify our suggested guidelines in a jointly authored correction, an option we eventually rejected to maintain our intended role as independent reviewers of the literature and its ongoing controversies. The journal eventually published a separate correction and further explanation (Lombard, Snyder-Duch, & Bracken, 2004).

The impacts of the SF and CAR studies continue. The original article referred to an online resource (Lombard, Snyder-Duch, & Bracken, 2003) that we established to summarize the article and provide updates as new evaluations of indices and tools became available. Nearly a decade later, I still receive email messages thanking us for the resource and asking questions about reliability. I was invited to give a talk at the Conference on Optimal Coding of Open-Ended Survey Data at the University of Michigan (Lombard, 2008). The materials, papers, and stories from both projects have been very useful in the classes I teach. Even this chapter represents an entirely unexpected outgrowth of the original structural features of television project. And it is possible that I will return to one of our original goals – comparing the television form from the now long ago 1995 with the present, a task that would be much easier for two reasons. The first is the amazing evolution since the mid-1990s of digital technologies for capturing and replaying images. Recordings could be created with home DVRs and transferred to a computer or, better yet, directly captured and recorded on a computer’s hard drive, and then analyzed with frame-by-frame accuracy using electronic time code in Final Cut Pro or other digital editing software.

Meta-tags could even be added to individual frames and found later via searches to speed the coding process. The second reason the recording and coding process would be easier today is that we have learned many lessons through the process of developing the original project.

Lessons Learned

So what were those lessons learned during the project? I think the most important ones were the following.

Be ambitious but realistic. We were right to start out designing the most creative and ambitious project possible, one that would answer all of our research questions and generate multiple research reports. Start with the ideal study and for the most part ignore constraints on your time, money, and other resources, and then be realistic as you reduce the scope and modify the design details to match those constraints. This is something that, in retrospect, we did not go far enough in doing. Researchers can get too attached to specific content analysis variables but, as with experiment variables, survey questions, and in all other forms of research, it's essential to prioritize.

Expect things to take longer. At nearly every stage of the structural features research unexpected issues arose to delay us. In fact, these delays were so substantial that three team members got married, four babies were born, and several people graduated and/or moved away during the course of the project. Underestimating the time needed to complete complex tasks is typical – it has an official status as Douglas Hofstadter's law (see Hofstadter, 1999). Even though it is difficult, however, researchers should always keep this problem in mind. One good strategy is to make a good faith estimate of how long major steps in the project will take and then add another 50% or 100%.

Do research together. This project would have been impossible for any single person to complete, and not just because content analyses require multiple coders. I would argue that, with important exceptions, a research group produces better ideas, accomplishes more, and provides a richer experience than single researchers working independently. Although group dynamics can be complicated and everyone's needs and preferences have to be thoughtfully considered, the increased efficiency and the ability to brainstorm, celebrate, and commiserate together is worth the effort.

Do research with students. At various times six doctoral, two master's, and three undergraduate students worked on the structural features project. Aside from the many benefits their participation contributed at every step, they – or more accurately all of us – were able to learn about research by actually doing it, fulfilling another important mission of a university. Project leaders also need to delegate specific sets of tasks to student team members so they learn as much as possible and gain a sense of "ownership" over the research. Besides, the leader simply cannot do everything.

Be organized. This project required an extra level of attention to organization and detail, with so many researchers; variables; sampling units; videotapes; coders; coding sheets and manuals; data storage and analysis software programs, formats, and files; and articles and presentations. But organization is an undervalued aspect of every research project. Keep detailed electronic records of everything (and printed copies as needed). Make backup copies, ideally via a real-time automated system such as the software provided with most external hard drives. Use shared online calendars, spreadsheets, and word-processing files (e.g., via Google Docs) to coordinate information accessible to and updatable by team members (this wasn't available in the mid-1990s). Devise naming conventions for electronic and hard copy files and folders so that you and others can find specific material when you need it. Follow these conventions even when you're in a hurry to get to other tasks – for example, don't put files in a generic folder to be sorted properly later. Document all procedures and instructions and make them easily accessible. Keep each major (and even minor) draft of most documents so you can refer to them later if necessary. Communicate constantly with the other researchers: send updates, ask questions, hold informational and brainstorming sessions, both online and especially in person (over coffee, snacks, lunch, or dinner – food always improves communication and creativity!).

Be flexible and creative. When we realized videotape stretches, we designed the anchor frame mechanism; when reliability was unexpectedly low for some variables, we modified the measures or figured out how indices could be combined to better represent the underlying situation; when we realized how much we had learned, we found new projects and venues for both publications and service to the field. Although it is not easy, researchers need to be flexible and creative, open to “outside the box” solutions and new opportunities that take the original plan in new directions.

Follow through. Although we persevered through many challenges for many years and the structural features project generated several conference papers and then indirectly more papers and publications, we (mostly I) failed to follow through quickly enough to produce publications of the original results. So my advice to others, which I continue to struggle to follow myself, is to not give up on or to let projects get cast aside in favor of new distractions. Most challenges, including negative peer reviews – there is always a critic or three out there you will not be able to satisfy – can and should be overcome.

Recognize trade-offs. Our initial belief that content analysis would be easier than other social science methods because it does not involve human respondents or subjects was naive. Every research choice represents a trade-off – time versus money, validity versus reliability, depth versus breadth, problems with participants versus problems with coder reliability. There's no “free lunch”!

Enjoy it. Despite the obstacles and frustrations along the way, the research I've described here was extremely rewarding and a great adventure. Given the chance, I would do several things differently but I would definitely do it again. My most important advice to other researchers is to follow your interests and passions in selecting topics and conducting research – to enjoy it. Life is too short to do anything else.

Text-Based Approaches to Qualitative Research

An Overview of Methods, Process, and Ethics

Sara McKinnon

ABSTRACT

This chapter provides an overview of the research process of text-based qualitative research. The chapter not only explains what it means to work with texts in a qualitative manner, but outlines the various options researchers have at their disposal in trying to answer the research questions that most interest them, including rhetorical methods, discourse analysis approaches, and ethnographic methods. The chapter also provides readers with a step-by-step overview of the process of doing text-based qualitative research, ending with a discussion of ethical considerations in qualitatively analyzing texts.

One of my most vivid memories from graduate school was the answer that I received from a professor when I asked, “How do you analyze a text?” He responded without pause, “You find an interesting text and look for what makes it interesting!” This answer was unsatisfying at best. Only later in my qualitative research classes did I begin to get a sense of what I should do with the primary sources that I had collected and wanted to write about.

Now, as a teacher myself, I find my students asking similar questions – “How do you find a text worthy of analysis?” “What makes a text interesting?” and “Once

you have it, what do you do with it?” – only to find those same unsatisfying answers slipping off my tongue. In acknowledgment that these answers can confound more than they clarify, this chapter aims to outline what it means to do text-based qualitative research. The chapter will not only explain what it means to work with texts, but it also outline the various options researchers have at their disposal in trying to answer the research questions that most interest them. Furthermore, the chapter will offer a step-by-step overview of the process of doing text-based qualitative research so that when you hear “You just analyze it!” again you know what that means.

Text-Based Approaches to Qualitative Research

Broadly speaking, qualitative researchers seek to understand the communicative actions of people in particular contexts and the meanings associated with those actions. Communicative actions happen when people use symbols to express something in their life-worlds; these actions come in a range of forms – from the things we do and say in interpersonal encounters, to performances and practices that demonstrate our social, cultural, or political group affiliations, to the messages that media assemble for our consumption. While many qualitative researchers assemble instances of communicative action from people themselves, through methods of data collection such as interviews, focus groups, and observation, other qualitative researchers examine texts as sites of people’s use of symbols. A *text* can be understood as any instance where symbols are being used to convey meaning to an audience. In this vein, texts may be written words in the strict sense of the term – such as books, magazines, manifestos, or pamphlets – but they may also be verbally delivered speeches, music, television sitcoms, photographs, or buildings.

While qualitative researchers may find a text that is interesting to them and analyze it, they do so recognizing that all texts are fragments of something larger. “Texts,” as Michael Calvin McGee explains, “are understood to be larger than the apparently finished discourse that presents itself as transparent. The apparently finished discourse is in fact a dense reconstruction of all the bits of other discourses from which it was made. It is fashioned from what we can call “fragments”” (McGee, 1990, p. 279). In other words, the texts that appear so complete on first glance are incomplete pieces, or representative parts of something larger that researchers call discourse. For many qualitative researchers, *discourse*, or the available language that people have to talk about some phenomenon or to express something, is what researchers are trying to explain and interpret when they analyze particular texts. While discourses are never complete, understanding their scope and the dominant modes of expression within them helps researchers to illuminate the range of possibilities that are before us when we communicate. To understand this range, scholars examine texts and the discourses they participate in against the particular social, cultural, and political con-

texts in which they circulate. *Contexts* must be thought of not as one-dimensional environments where communicative action happens, but as productive forces of the discourses that we turn to in order to share and express meaning. In this way, a component of our analytic attention as qualitative researchers of texts must be toward the contextual factors that constitute the way people use language.

Finally, qualitative scholars work to understand what texts *mean* for the people who use them. As Thomas Lindlof and Bryan Taylor (2002, pp. 5–6) write,

For the qualitative researcher, humans infuse their actions – and the worlds that result – with meaning. We are, at root, trying to make sense and get by. In this view, meaning is not a mere accessory to behavior. Rather, it saturates the performance of social action – from our imaginations of possibilities to our reflection on accomplishments.

To do this, qualitative researchers turn to the tools of research that allow them to describe, understand, and interpret the significance of communicative messages actions within a particular sociocultural and political-economic context. Specifically, qualitative researchers ask questions about *how* and *why* texts circulate within a given context in the ways that they do. Furthermore, qualitative researchers interpret what these texts mean within particular contexts and for particular audiences.

What is so exciting, and sometimes daunting, about using texts to do qualitative research, is that researchers have a diverse range of approaches that they can deploy to examine the qualitative dimensions of particular texts. In the next section I will summarize a few of the primary approaches that researcher have at their disposal. Specifically, I will review rhetorical approaches, discourse analysis approaches, and ethnographic approaches to studying texts.

Types of Text-Based Approaches

At the most general level, scholars who use qualitative methods to look at texts are doing textual analysis. While there are other names for textual analysis, such as criticism, critical analysis, or close reading, these approaches share similarities in their methodological processes. As Barry Brummett (2010, p. 9) explains, textual analysis involves “mindful, disciplined reading of an object with a view to deeper understanding of its meaning.” In order to do the disciplined reading, scholars who use textual analysis study existing *theory*, or attempts at describing and explaining what something is, the way it works, or what it means, in order to know what has been said previously about a particular object or phenomenon. This existing theory gives the analyst special insight into the symbolic actions, nuances in meaning, and textual forms that are present in the text. Studying theory also provides analysts with ideas about what their own text might say concerning culture, politics, society, or the world around them more generally.

Once analysts have an object that they want to examine and a theory or set of theories that inform their reading, the analyst then turns to particular methods of reading, or analysis. As Brummett (2010, p. 37) explains, “the method is the plan for thinking and action” which offers us tools for implementing that plan. For scholars working with texts, these tools should call our attention to nuances in both the form and the content of the object. When we look at questions of form, we examine how the object is arranged, how it is patterned, and the internal structure that organizes the content. Some common elements of form include narrative structures in the text, the genre that the text may fall within, and personas or groups of people who are addressed (or not addressed) in the text.

Questions of content call our focus to what the text says, or does. Using theory as the lens, we examine the text for key arguments, undergirding ideologies, and the specificities in the way language is used to convey meaning for a particular audience. Importantly, the theory or theories we turn to will shape the elements of form and content that we are drawn to see and write about. As we will see in the next section, rhetorical approaches offer a more specific form of textual analysis that call us to pay attention to the practical functions of language.

Rhetorical Approaches

At one point in recent history rhetorical criticism seemed to be moving in the direction of quantitative approaches to research in its goals of identifying the efficacy and effects of particular rhetorical texts and rhetoricians. Today, however, rhetorical critics largely see the work of analysis as a qualitative and interpretive project. Broadly speaking, rhetorical criticism offers tools to analyze what language does in our lives. Scholars of rhetoric posit that language not only shapes how we know and experience the world around us, but also how we use language in our social worlds to influence others, deliberate, make judgments, expand possibilities, and sometimes reform social systems in need of repair (Foss, Foss, & Trapp, 2002). These functions of language are of central concern to rhetoricians, for as Stephen Lucas (1981, p. 20) writes, rhetorical critics “are concerned above all with what messages do rather than what they are.” Examinations of such language deployments focus not only on the particularities of symbol use, but also on how bodies, voices, emotion, images, and objects serve as discursive vehicles of social influence when paired with language. In this way, rhetorical criticism is a method that provides the means to analyze not only discourse itself, but also *how* messages are deployed through the body, voice, images, and objects, and *what* such messages do.

One common point of confusion is where to find messages that are significant to our social worlds, and thus worthy of analysis. While early studies of rhetoric focused primarily on rhetorical texts of the past – often in the form of the speeches or writings of well-known figures – contemporary rhetorical critics include a vast range of rhetorical texts within their repertoire. Certainly texts such as governmental policies,

congressional deliberations, and legal decisions are sites where language is used practically and in important ways, but popular texts such as movies, sports broadcasting, magazines, and participatory media also interest rhetoricians as texts of investigation. For example, Dana Cloud (1996) examines biographical narratives of Oprah Winfrey as her object of inquiry, arguing that Winfrey is rhetorically positioned as a token whose success proves that US American meritocracy exists without barriers for women and people of color. Greg Dickinson (2002) takes the spatial dimensions of Starbucks, the well-known caffeine-recharge watering hole for millions of consumers, as his text of investigation to argue that Starbucks rhetorically constructs authenticity through its use of color, music, artwork, smell, and language to make customers feel like they are getting the real deal when they spend \$5 on a cup of coffee. Darrel Enck-Wanzer (2006) argues that trash, literal garbage, is a rhetorical construct for Puerto Ricans living in the Bronx in the 1960s to get city officials in New York City to begin to pay as much attention to the cleanliness of the streets in the Bronx as they did to the streets of Upper West Side Manhattan. These examples demonstrate the breadth of rhetoric's purview; quite simply, rhetorical messages worthy of analysis may be found anywhere. The task of the rhetorical critic in choosing a text worthy of inquiry is to justify what makes these objects interesting, or in need of analysis, and, second, to identify what the discourse is doing.

Another challenging part of doing rhetorical criticism is figuring out what method of rhetorical analysis will best suit the critic's objectives and the rhetorical object. As Dilip Gaonkar (1990, p. 303) explains in assessing the state of rhetorical criticism, rhetoric has witnessed not only what he calls "the globalization of the object" but also a diversification of methods for analyzing rhetorical objects. Just as there is no longer merely one type of object that rhetoricians analyze, there are also a plethora of methodological tools for rhetoricians to turn to in doing their analytic work. For example, social movement criticism (Griffin, 1952; Simons, 1970), genre criticism (Campbell & Jamieson, 1995; Ware & Linkugel, 1973), and narrative criticism (Fisher, 1984) emerged early in the field's history as options for doing rhetorical analysis. A particularly fruitful avenue for media scholars using rhetorical criticism has been the methods of criticism that allow them to centrally investigate relations of power, ideology, and modes of resistance present in texts or the way audiences engage with text. These methods include critical rhetoric (McKerrow, 1989, 1991; Ono & Sloop, 1992), ideographic criticism (McGee, 1980), and feminist criticism (Campbell, 1973; Davis, 1998; Dow, 1995, 1997) among others. Notably, they have enabled scholars to examine the discursive and ideological underpinnings of mediated representations of war (Crenshaw, 1997; Jordan, 2007), iconic imagery (Calafell and Delgado, 2004; Taylor, 2003), and the way that the distinctions between popular, consumer-based culture and political life become increasingly blurred and undefined (Anderson & Stewart, 2005; Cobb, 2011).

While using a specific type of method is a common approach of the rhetorical critic, others argue that the critic himself or herself is the method and thus the rhetorical analyst does not need a prescriptive *a priori* method (Black, 1965). In

conversation with qualitative researchers who see the researcher as the “human instrument” of research, Edwin Black famously recognized that the rhetorical analyst brings to the text a unique vantage point to see the text as a reflection of the external reality around the text. While this open approach to method is still used by many in the field, others have refined the idea that the critic is the method to focus on theory as guiding the process of describing, explaining, and interpreting what language is doing in a text. Michael Leff, a strong proponent of what he describes as “the emic approach,” calls on rhetoricians to see rhetorical criticism as an interpretive process. As he explains, the goal of rhetorical criticism

is explanation, and therefore the emic stance begins and ends with the particular object of study. Theoretical principles enter at the intersection between the object and the assignment of meaning to it, but such principles are so closely connected with the object of study that they are not easily isolated in abstract form. (Leff, 1980, pp. 348–349)

More recently, James Jasinski (2001, p. 256) called this approach “conceptually oriented criticism,” which he explains “proceeds more through a process of *abduction* which might be thought of as a back and forth tacking movement between text and the concept or concepts that are being investigated simultaneously.” This approach recognizes that we enter the research process with particular views of the world, life experiences, knowledge, and interests that influence the questions, ideas, and issues that we will be drawn to examine. This background also leads us to particular texts, sets of texts, or even fragments of texts to analyze against and through our questions and interests (McGee, 1990). Then we begin the process of analysis, or close reading of the texts, for what language and discourse is doing and possibly turn to specific techniques of close reading explained above (Brummett, 2010), such as analyzing the object for its use of narrative or metaphor. Importantly, neither our past experience, theoretical influences, nor the reading techniques we choose dictate the direction of the theory generated from the analysis; instead, these things are tools that help us do the work of interpretation.

Our experiences and past knowledge are important as they alert us to what is interesting about the text in relation to its audience and the context, as well as to what the text is doing with language and discourse. While social scientific scholars attempt to deploy research methods objectively, or as free as possible from researcher bias, qualitative researchers embrace the subjectivity of the research process. This means that, rather than seeing the researcher’s background and interests as a hindrance, qualitative researchers use these aspects of the researcher as a source of insight and information about the text. Because qualitative researchers embrace the subjectivity of the research process, no two analysts will read a text in the same way. For example, a scholar whose intellectual influences are gender theories may analyze a speech by Abraham Lincoln and see a particular type of masculinity evoked or forming (Zaeske, 2010), while a critic who finds photographs and images fascinating

may be drawn to analyze texts that are rich in imagistic descriptions of Lincoln's character (Finnegan, 2005). These different analyses add to what the interested communities know, or how they think about Lincoln as a rhetorical figure. In this way, neither analysis is biased or more right than the other; instead they are different pieces of the puzzle. With a sense of how qualitative scholars use rhetorical approaches, I will now turn to discuss a qualitative approach that analyzes texts against their broader discursive and social contexts.

Discourse Analysis

While rhetorical analysis emerges out of the discipline of communication studies, linguistics offers yet another set of text-based approaches to do qualitative research – under the umbrella term of “discourse analysis.” This method allows scholars to analyze discourses alongside their discursive and social practices. Discourse, in this approach, primarily refers to any text, spoken or written, that deploys language, although increasingly discourse analysts are looking to non-language-based symbols, such as objects or artifacts, for meaning alongside the language-based discourse. As Norman Fairclough (1995, p. 4) explains, discourses rarely manifest in isolation. Rather, “texts in contemporary society are increasingly multi-semiotic; texts whose primary semiotic form is language increasingly combine language with other semiotic forms.” This means that discourse is polysemic, or that the same discourse might emerge in numerous forms. For example, a number of analysts have recently taken up the post-September 11 “terrorism” discourse as it emerges in a range of texts including presidential and political speeches (Bartolucci, 2012), policy and law (de Beaugrande, 2004; MacDonald & Hunter, 2013; Simone, 2009), documentaries (Mylonas, 2012), and news media (Featherstone, Holohan, & Poole, 2010; Roy & Ross, 2011). What is interesting about this discourse, as Valentina Bartolucci (2012, p. 563) writes, “is its extraordinary level of consistency within different genres, spaces and times. The same set of words and linguistic constructions are used, reproduced and finally naturalized, eventually coming to be seen as common sense.” Despite being polyvocal in form, the terrorism discourse in President Bush's speeches bears striking resemblance to the way it is deployed by the news media, in law and policy, and as David Machin and Theo Van Leeuwen (2009) demonstrate, even to the way this discourse appears in children's toys. Furthermore, these scholars demonstrate that the meaning of terrorism is surprisingly similar in different national contexts. Karmen Erjavec and Zala Volčič (2007) illuminate this point, showing that terrorism discourse is taken up by Serbians after September 11 to rearticulate Serbian violence against Muslims during the 1990s as understandable and justifiable. Importantly, their language is hauntingly similar to the words of President George W. Bush.

A second focal point for discourse analysts is the discourse practice, which concentrates attention on the circuit of culture through which the text circulates, from

its production to its interpretation and consumption. Analysis at this level involves attentiveness to how people produce and interpret texts. This may include, for example,

detailed moment-by-moment explication of how participants produce and interpret texts, which conversation analysis and pragmatics excel at, and analysis which focuses upon the relationship of the discursive event to the order of discourse, and upon the question of which discursive practices are being drawn upon and in what combinations. (Fairclough, 1995, p. 134)

Focus on the practice allows scholars to understand how specific discursive moments participate in broader conventions, genres, and patterns of interaction (Wood & Kroger, 2000). For example, Fairclough (1993) investigates the way universities deploy market-based discourse practices, through encouraging employees to “self-promote” their research, “sell” candidates, and “play the game.” These particular instances of discourse, he explains, are generated through market logics and function to constitute universities – places that were once designated for knowledge production and critical engagement – into contexts for consumption.

Finally, discourse analysis calls scholars to examine the way that discourses and discourse practices participate in broader sociocultural systems and structures of meaning (Fairclough, 1995). This level of analysis focuses the analyst’s eye on the function of discourse, or what it is doing within the organizations, institutions, and societies where they circulate. This level of analysis is the broadest level used by discourse analysts, and also perhaps the most important as discourse analysis *cannot* be discourse analysis without an examination of the sociocultural practice of the discourse. Analysts interested in the sociocultural implications of discourse have looked, for example, at the discursive confluences of immigrants, refugees, and asylum seekers with gangs, criminals, and thieves, which often comes to justify policies of amplified exclusion and surveillance against these communities (Baker, Gabrielatos, Khosravini, Krzyanowski, McEnery, & Wodak, 2008; Hernández & Romero, 2013; Khosravini, 2010; Teo, 2000; Van Der Valk, 2003; van Dijk, 2000; Van Leewen & Wodak, 1999). They have also examined the ways in which the repetitiveness of gendered norms in institutions such as sports (Mean & Kassing, 2008) and education (Sauntson, 2007; Wharton, 2005) function to constrain the range of gender expressions possible to a limited few. Finally, scholars have examined the emergence of nationalistic discourses across a diverse set of locales, working to understand how a nation’s history, relationships with other nations, and aspirations for the future matter to the way it constructs a sense of itself (Crawford, 2012; Han, 2011; Mosheer, 2012; Ruiseco & Sluneko, 2006).

Discourse analysis resonates with some of the other text-based qualitative methods summarized thus far, but methodologists claim that the approach offers unique tools to the scholar and student of texts. As Fairclough (1995, p. 97) explains, according to

this approach, “the link between the sociocultural practice and text is mediated by discourse practice.” He continues:

How a text is produced or interpreted, in the sense of what discursive practices and conventions are drawn from what order(s) of discourse and how they are articulated together, depends upon the nature of the sociocultural practice which the discourse is a part of (including the relationship to existing hegemonies); the nature of the discourse practice of text production shapes the text, and leaves “traces” in surface features of the text; and the nature of the discourse practice of text interpretation determines how the surface features of a text will be interpreted.

In other words, each level of analysis – discourse, discourse practice, and sociocultural practice – builds upon the next, such that each level offers a potentially unique purview into the way language functions to construct people’s sense of what is within particular institutions, organizations, and societies.

Importantly, this embedded process of analysis has led to new approaches to studying texts, or what we might understand as offshoots of a broader discursive approach to doing qualitative research. These include, among others, critical discourse analysis, which narrows the process of analysis in on the way power, domination, and ideology circulate through discourse (Fairclough, 1995); the discourse historical approach, which emphasizes analysis of fields of action (Reisigl & Wodak, 2009), and social semiotics, which calls our attention to the semiotic action involved in each message, discourse, or image (Aiello, 2006; Van Leeuwen, 2005). The final approach discussed here takes text-based qualitative approaches full circle, back to qualitative methodology’s anthropological roots in the form of ethnography.

Ethnographic Approaches

Ethnography can be thought of, literally, as a writing up of culture. Historically this was the work of anthropologists who would go into the field, often somewhere far away from where the researcher lived and worked, to examine the ways of life, rituals, and patterns of a particular group of people and then write up an account of this community’s “culture.” In 1973 noted anthropologist Clifford Geertz ruptured this framework of doing ethnography by suggesting that culture was all about communication, and that culture should be studied via semiotic analysis, or in the way that a particular community uses language. Geertz (1973, p. 5) explained this as an analysis of the “webs of significance” that undergird what a community says and does:

The concept of culture . . . is essentially a semiotic one. Believing, with Max Weber, that man is an animal suspended in webs of significance he himself has spun, I take culture to be those webs, and the analysis of it to be therefore not an experimental science in search of law but an interpretive one in search of meaning. It is explication I am after, construing social expressions on their surface enigmatical.

Later in the essay, Geertz would elaborate on the process of unearthing meaning:

Our double task is to uncover the conceptual structures that inform our subjects' acts, the "setting" of social discourse, and to construct a system of analysis in whose terms what is generic to those structures, what belongs to them because they are what they are, will stand out against the other determinants of human behavior. In ethnography the office of theory is to provide a vocabulary in which what symbolic action has to say about itself – that is, about the role of culture in human life – can be expressed. (1973, p. 27)

This approach to researching culture profoundly impacted the way communication scholars examined symbol use in particular communities. We not only see this early on with scholars using an ethnography of communication approach to understand the types of communication that were unique to particular groups (Hayes, 1976; Katriel & Philipsen, 1981; Philipsen, 1975), but there were also early calls to combine ethnographic methods with text-based methods. Dwight Conquergood was in the vanguard in drawing scholars' attention to the relationship between ethnographic and text-based methods. In particular, Conquergood made connections between the work of ethnographers and that of scholars interpreting meaning from text, explaining that those who analyze culture and those who analyze texts similarly use methods that are "characterized by a crucial sense of timing and improvisation, an ability to seize the opportunity and play the moment" (Conquergood, 1992, p. 82). Additionally, we can say that ethnographers and text-based scholars alike are interested in symbolic action, the context from which the text emerges, and the meanings that flow through these actions.

With these similarities in mind, a number of scholars have recently begun conceptualizing what it might mean to do text-based ethnographies. These formulations have come in the form of virtual, online, or digital ethnographies (Boellstorff, Nardi, & Pearce, 2012; Fullerton & Rarey, 2012; Howard, 2011; Kozinets, 2010; Lindlof & Shatzer, 1998) and rhetorical ethnographies (Chávez, 2011; Hess, 2011; Middleton, Senda-Cook, & Endres, 2011; Pezzullo, 2001; Salazar, 2009). What these approaches offer is a way of combining a focus on the way culture is constructed through language and attentiveness to context with the tools of close reading offered in textual analysis.

While these works differ in focus – some looking at the organizing strategies of activists, others analyzing the ways that people make community through texts – they share two important characteristics that are unique to text-based ethnographies. First, the blending offers text-based scholars dynamic and dialogic ways of examining how discourse happens in the moment. As Middleton et al. (2011, p. 401) explain, this happens because field methods give text-based scholars a sense of what discourse looks like "live": "By analyzing 'live' rhetorics, critics are able to bring to the fore and capture rhetorics whose everyday nature renders them fleeting at best." Additionally, it allows scholars intimate insight into how people come to settle on the discourse

they use in the public. Chávez's research (2011) concerning the coalitional strategies of US immigration and lesbian, gay, bisexual, and transgender (LGBT) activists demonstrates this point nicely, as she argues that rhetorical scholars must look at the internal, away-from-the-spotlight workings of activists and organizers to gain insight into the rhetorical resources at their disposal, as well as the contextual and relational constraints that impact what discourse they can use in the public.

Another strength of this blended approach is that it allows us to see nuances of context – including space and place, but also the historical political-economic relations that bear down on the communicative actions we examine. Dickinson, Ott, and Aoki (2006) rhetorically examine the Plains Indian Museum in Wyoming as a cultural text that constitutes White audiences through what they call a rhetoric of reverence. Specifically, they explain that “the museum creates a space of memory in which distant Plains Indian history and culture are placed on view, honored, and valued,” but White museum goers are never faced with interrogating their involvement in historical and present-day racism (Dickinson et al., 2006, p. 41). Ethnographic observation of the museum and White audiences' engagement with the museum enabled these researchers to ask questions, and to come up with interpretations that reflected on the museum's constitutive powers. In this way, space and place are rhetorical in that they compel our imaginations of ourselves. Were Dickinson et al. to have merely read about the museum – or even analyzed its web-based features – they most likely would not have been able to consider such contextual elements of rhetoric.

A final strength of the ethnographic text-based approach is that it allows the symbol users to speak back, and in part define what the communicative actions mean to them. As Middleton et al. (2011, p. 389) explain, rhetorical field methods are useful for “attempting to create more equitable representations of marginalized voices” and for identifying how those voices might enter public discourse toward transformative change. Additionally, these methods give participants a chance to speak back and fill in the gaps. Robert Glenn Howard's (2011) research provides a great example of this as he examines community making among Protestant fundamentalists in online environments. Combining ethnographic methods of interviewing and observation with the rhetorical tools of close textual analysis, Howard's work demonstrates the ways in which rhetoricians can gain insight into communicators' motivation, intention, and inventional process by observing their message choices and then asking them to reflect on the choices through interview questions. In Howard's analysis, for example, participants' actions and explanations serve as the discursive material that demonstrates not only what an evangelical social movement looks like, but also what it means to them. These moments show that one of the strengths of using ethnographic methods in rhetorical research is that such methods allow the voices we represent to speak with, and sometimes speak back to, scholarly interpretations and analyses of the data.

Having provided a description of different types of text-based qualitative research, I turn now to address the step-by-step process of using these methods. This

explanation is certainly one approach among many possibilities, but it should give the reader a sense of what researching with texts looks like.

Doing Text-Based Qualitative Research

As noted above, there are definite differences in the foci of the approaches discussed so far, in the questions they ask, and in the specific methodological tools they use but the process of using these approaches is roughly the same. For each approach there are basically two places where the researcher might begin: with the object or with the question. Those who begin with an object are usually drawn to it because of its political, social, or cultural import, or because it is just plain puzzling. If you begin with a text, the next step is to try to delineate what the text might be saying or doing. It is at this point that scholars draw upon their existing knowledge, world-views, and experiences to understand what sorts of questions might best be explored and explained through an examination of this object.

Another route in doing qualitative research is to begin with a question, a concern, or an issue that sparks your interest. Scholars who begin with a question move quickly to think about what sorts of texts, people, and contexts might best help them examine the issues at hand and come up with answers. As stated earlier, this might be a single text, an assemblage of texts, or even a combination of different types of data that the researcher examines in order to come up with answers to the questions they are asking.

Once the researcher has a sense of the text and the theoretical focus of her or his analysis, she or he can then move to the actual analysis of the object. At this stage the research process is most similar to conducting qualitative research using methods that involve human interaction. The researcher is looking for codes, themes, patterns, and dynamics that exist in the texts' form and content much like a researcher would do when analyzing field notes or an interview transcript. The objective of this process of analysis is to derive explanations of what the text is doing, or how the text operates, in accordance with the parameters given through the researcher's theoretical and methodological choices. As David Altheide (1996, p. 16) explains, at this point, the data process should be

systematic and analytic but not rigid . . . Categories and variables initially guide the study, but others are allowed and expected to emerge throughout the study, including an orientation to *constant discovery* and *constant comparison* of relevant situations, settings, styles, images, meaning, and nuances.

What this systematic yet flexible process of analysis should look like is often where scholars and students interested in qualitative research get most confused. The truth is that there are a plethora of analytic tools available to the qualitative researcher.

David Altheide (1996) recommends beginning with the protocol, which is a series of questions, themes, and categories that the researcher believes might be present in the data, or at the very least might be interesting to ask of the data. A more inductive process, however, might begin with coding and categorization.

An inductive process begins with coding the data, or making shorthand notes to label what the data says, organizing the data into themes, and generally beginning to look for the patterns, sense making, and structure that is theoretically and culturally significant. As Lindlof and Taylor (2002, p. 219) explain, during the coding process the “analyst usually goes through the texts (fieldnotes, transcriptions, documents) line by line and marks those chunks of text that suggest a category.” The general purpose of this process is to link the sections of data that fit within a broader category with a shorthand code to help you remember to consider the significance of that data for the overall category. Quite often, researchers who are coding start with the questions “What’s going on here?” or “What’s happening in this text?” as they try to make sense of the text. As they read the text over and over, looking for cultural or theoretical meaning, they begin to see patterns emerge, themes that are indeed meaningful, which become significant categories that bring the researcher one step closer to identifying what the text is saying and doing.

Categorization happens when we assign meaning to particular components of our data by identifying it as representative of some general or specific phenomenon of interest, and put that data alongside other data we have that do the same thing. These categories sometimes emerge from existing literature, but they can also emerge because we see patterns, or themes of interest, in the data set. Importantly, merely having categories does not mean that the researcher is ready to write up the study. The researcher still needs to interpret the significance of those categories toward making an argument.

Interpretation is the next phase in the research process. At this point the researcher has a good sense of the data. She or he has coded and categorized the data, and reached the point of what qualitative researchers call *saturation*, or the moment when the researcher no longer finds anything surprising when coding and categorizing. Reaching the point of saturation indicates to the researcher that it is time to move to the next phase of research. Interpretation then moves researchers to build theory, in the form of arguments, that provide partial answers to the questions and problems that first inspired them to analyze the texts. At this point it is often necessary to turn back to the scholarship on the topic in order to read and ascertain what is already known in the scholarly community. Researchers work to build interpretations that add to that body of scholarship rather than replicate existing knowledge. Once the researcher has a strong grasp of the extant and relevant literature, as well as an argument that contributes to the literature, the next step in the research process is to write up the research.

While researchers go about this step in different ways, the writing phase involves three processes: developing a setup, accounting for one’s methods, and writing the analysis. The setup in this instance refers to the rationale, which demonstrates

the importance of the research, a justification for the particular research question and/or argument, and finally an explanation of how the research fits within and contributes to the extant body of scholarship. This setup may be found in the introduction and in the review of literature, its purpose being to create a platform that contextualizes the analysis and its contributions.

Not all text-based qualitative researchers include an accounting of their method in the write-up of their project, but they should be able to articulate how and why they did what they did during the research process. When a method section is present it typically includes a discussion of how and why particular texts were chosen, the specific research questions that guided the analysis, the process of analysis including the development of codes and categories, as well as any additional context that might be needed to understand the analysis.

The analysis section is where the researcher finally reports on the original research conducted. One of the key challenges in this period of the research is figuring out how to use the data appropriately. Researchers should allow the data to guide the evidencing of their arguments, but they also must not lose their analytic voice in the process. Quite often, analysis sections foreground the data so much that the author's argument ends up being more descriptive than analytical. Instead of merely describing what's happening, researchers should use data in the analysis section to further their argument, which means deploying it to illustrate their interpretation of the particular situation.

Ethical Considerations

In this chapter I have provided a broad overview of text-based qualitative research methods with a specific focus on the numerous approaches that scholars have at their disposal and the specific steps involved in the process of doing qualitative research using texts. To conclude, I would like to address the ethical considerations of conducting qualitative research using texts.

Qualitative researchers who work with humans have a long history of debating what should be the proper ethical standards in research. Scholars who examine texts, in contrast, rarely question what ethics should guide the practice of collecting, analyzing, and writing up research. This, I believe, is a mistake and I would like to offer a set of questions text-based qualitative researchers might consider in developing ethics to guide the research process. First, we might ask ourselves "Why am I doing this research?" or "Why is this research necessary and useful?" These questions, if seriously considered, can help researchers to understand the *motivations* that guide the research practice. Many feminist and critical scholars, for example, take the motivation of opening space for marginalized voices, perspectives, and knowledge as the central purpose of their work (Davis, 1998; Flores, 1996). Additionally, many scholars

are guided by utilitarian assumptions of the greater good or pragmatic goals of making applied change in the social worlds around them (Madison, 2005). No matter the motivation, researchers should be able to explain how that motivation guides what texts they choose and how they analyze them.

Additionally, we should ask ourselves “How am I connected to this research topic?” or “What is my positionality, or social location, in relation to this research topic?” These questions necessitate that researchers remain *reflexive*, or mindful of their relationship to the research topic, so that they can account for how their own experiences, knowledge, identities, and worldviews shape not only what they see in the data, but also how they interpret it. In examining the politics behind naming practices for Chinese women, Wen Shu Lee (1998, p. 297) provides an excellent example of how text-based researchers might integrate reflexive practices into their work:

Who am I and who am I not? I was born into the Lee family in Taipei, Taiwan. My name, Wen Shu was given by a paternal great great uncle, who was venerated as a scholar of high moral standards and as a patriarch who made major decisions for the extended family. I don't think my mother was consulted about my name.

Lee proceeds to address the politics involved not only in how she came to have her name, but in what happens to her name when she moves from Taiwan to the United States. This reflection helps the reader to understand her social location as an analyst of the rhetorical dimensions of naming practices, and also why naming practices matter.

Next, researchers might ask themselves, “Am I letting the text or data speak?” in order to address the ethic of *representativeness*, or how completely the analysis reflects the data. This question helps researchers pay attention to the ways in which they may be strategically choosing parts of the data that support their view, while ignoring data that contradict their interpretation. Additionally, this allows researchers to evaluate whether they have analyzed enough of the text to know that the most complete picture of the data is being represented in the analysis.

Finally, text-based qualitative researchers should seek to develop a deeper and more complex *understanding* of the subject matter they address by asking the following questions: “Does this analysis provide a more complex picture of the issue, text, person, or event than was previously available?” “Have I engaged in any problematic constructions of the people and communities I talk about in this research?” and “Does this analysis reflect and honor the cultural values and experiences of the people and communities I talk about?” These questions guide the researcher to evaluate whether the research enhances and illuminates the way we think about and understand people's lives, but it also calls us to question whether our own representations rely on discourses, beliefs, and stereotypes about groups that may objectify, exoticize, silence, or disempower the people we represent in our work.

Analyzing Text

The Cultural Discourse in Ethnic Food Reviews

Elfriede Fürsich

ABSTRACT

This chapter demonstrates how to conduct a textual analysis. I employ textual analysis through a cultural critical lens and illustrate this method with an analysis of food reviews. First, the method is defined and central theoretical tenets are explained. Then I outline the methodological process of this qualitative method from searching for a topic, establishing a theoretical background, selecting data, and presenting evidence to building a line of argument. As an example, I analyze newspaper food reviews of ethnic restaurants. This analysis is embedded in three theoretical contexts: the role of media in creating national identity; the essentializing contradictions of authenticity and culture; and the problematic “us versus them” dichotomies of international journalism.

Textual analysis has become one of the more popular methodologies for cultural critical media scholars. While the method is employed under various names, what all approaches have in common is that the method concentrates on qualitative interpretations of cultural output. For media scholars, the main data for a textual analysis is media content such as newspaper or magazine articles, television shows, radio programs, Internet sites, or computer games. Textual analysis draws on qualitative interpretive research traditions and critical theory.

This chapter demonstrates how to conduct a textual analysis. I employ textual analysis through a cultural-critical lens and illustrate this method with an analysis of food reviews. First, the method will be defined and introduced. Then I outline the methodological process of this qualitative method from the search for a topic, the establishment of a theoretical background, data selection, and the presentation of evidence to building a line of argument. Expanding on an exercise I used in the classroom, I analyze newspaper food reviews of ethnic restaurants. This analysis is embedded in three theoretical contexts: the role of media in creating national identity; the essentializing contradictions of authenticity and culture; and the problematic “us versus them” dichotomies of international journalism.

Defining Textual Analysis

With the cultural-critical turn in media studies more than 30 years ago, an increasing number of scholars rejected the social science paradigm of research along with quantitative methodology. Quantitative content analysis was criticized for remaining on a descriptive level and for evaluating language out of context. Instead, cultural-critical scholars tried to find a way of exploring content in its “natural” occurrence – words or images as they are expressed and received in a specific web of meaning. Drawing on a long line of qualitative research and interpretive approaches, textual analysis was often positioned in contrast to traditional content analysis, as it was seen as “a type of qualitative analysis that, beyond the manifest content of media, focuses on the underlying ideological and cultural assumptions of the text” (Fürsich, 2009, p. 240). These defining distinctions indicate the influence of the humanities, especially semiotics, film studies, and literary analysis, and of discursive interpretive approaches on the development of textual analysis.

In line with understanding media as “clues to the general culture” (Du Gay, Hall, Janes, Mackay, & Negus, 1997, p. 11), textual analysis has become a methodology that attempts to reconstruct the structures of feeling (Williams, 1974) – that is, the prevalent ideologies permeating a particular historical and cultural moment – that make a specific type of coverage possible. Researchers infer from specific media content how the people who produced the content and people who are addressed as audiences create shared meaning. The “underlying cultural and ideological assumptions” mentioned in the definition above are therefore the aspects in the text that can be analyzed to understand how ideology and common sense are constructed at any given time.

Textual analysis in the cultural-critical paradigm follows the principles of interpretive research (such as naturalistic inquiry). Textual analysts probe a research question inductively by finding patterns in the empirical material. These patterns lead to the interpretations and developments of explanations and theories grounded in the back and forth between observation and contextual interpretation. Textual scholars use

open coding, not predefined codebooks, to organize, condense, and interpret their material: they decide on specific codes based on observation of patterns in the text.

Methodological Assumptions

Three epistemological and ontological concepts are essential for understanding textual analysis as a method.

Open Text, Multiple Readings

The “text” in textual analysis denotes a semiotic and cultural understanding of cultural output. Central here is Roland Barthes’s understanding of text (1957/1972, 1977). Barthes positioned the rich, complex concept of text in contrast to the idea of a fixed *oeuvre*, which was traditionally considered the result of cultural production. In conventional literary studies, a critic’s task was to find the “true” meaning in a picture, book, or other artistic production, to decipher what the author “really” meant. In contrast, Barthes, and, consequently, the movement of poststructuralism and deconstruction, radically interpreted or deconstructed texts as open artifacts whose meanings are constantly under negotiation because they can be interpreted in various ways: any cultural text is polysemic, that is, it potentially triggers multiple meanings. As Larsen (1991, p. 122) in an early theoretical argument about the importance of text analysis summarized: “The text, then, should not be regarded as a closed, segmented object with determinate, composite meanings, but rather as an indeterminate field of meaning in which intentions and possible effects intersect.”

The production of meaning in media content is complex and can involve words, images, and sounds as signifiers. However, accepting the readers as the principal creators of meaning does not lead analysts to the relativistic conclusion that any text can be interpreted in an unlimited number of ways since everybody seems to “get something else out of it.” Instead, as cultural studies scholars argue, meaning is not created as an individual independent activity but audiences create meaning in a social process and rely on “shared maps of meaning” (Hall, 1997, p. 29). The social creation of meaning allows media producers and audiences to make sense of the world in a specific cultural and historic context but also always reflects given power relationships and ideologies. Therefore, meaning is never fixed but constantly contested.

Since popular texts are considered polysemic, it is not the goal of a textual analysis to uncover the one “true” or even “hidden” meaning of a text but to offer a variety of possible readings of the examined material. Instead of finding hidden meanings, “subconscious” intentions of the producers, or biases of the text, the task is to understand what cultural and ideological assumptions were established at a specific time that allowed a text to be considered acceptable and become popular, even common

sense. For example, analyzing the internationally popular US sitcom *Friends* allows us to understand the dominant Western ideological conceptions of the late 1990s with regard to femininity and masculinity, the work ethic, and personal and professional success.

Thus, textual analysis interrogates content in its social and cultural context. What is of interest is the relation of media content to the overall dominant ideology. A textual analysis answers the question of how ideology is negotiated in the content: in what ways does the content maintain, reinforce, question, or even defy dominant ideology.

Reality as Constructed

Textual analysts also assume a particular relationship between reality and media. Traditional content analysis tries to understand how accurately the media portray reality. This method accepts the social scientific ontology of a world accessible through sense perception. Instead, qualitative scholars argue that media and society are interrelated and that various versions of reality are constructed (in the media and beyond the media). John Fiske's well-known statement explains this axiom. According to him, television is perceived as realistic, "not because it reproduces reality, which it clearly does not, but because it reproduces the dominant sense of reality" (1987, p. 21). Engaging in this ontological perspective, textual analysts accept the notion that what causes social action is not a pure, discernible reality but the idea of reality in people's heads. The ubiquitous media play a decisive role in establishing ideas of reality that are soon considered normal. The power of media lies in the creation of an accepted reality and common sense, but the media also have the ability to confront the *status quo*, as Schröder (2002, p. 100) explained: "Media content [is] an artifact and process by which society is both reproduced and contested." A central question for cultural critical scholars is the media's potential to challenge the common sense.

Representation as Constitutive of Media Discourse

When textual analysts interrogate certain depictions or portrayals in media content, they use the term "representation." The aim of many textual analyses is to explain what types of representations are prevalent. The cultural studies scholars Stuart Hall and John Fiske played a central part in developing this concept for media studies. It would fall short to equate representation with portrayal or depiction in a text. When Hall explained that "representations are constitutive for a text," he distinguished the concept from the social science idea that portrayals in the media are a more or less accurate reflection of reality. To account for the complicated relationship between reality and mediated reality, textual scholars analyze representation as complex practices of signification. This analysis involves, according to Hall (1997, p. 9), "actual

signs, symbols, figures, images, narratives, words, and sounds – the material forms – in which symbolic meaning is circulated.” It is important for the textual critic to understand how current representations relate to earlier established representations. As Hall (1997) and others argued, representations are historically bound in a chain of signification. For example, it can be interesting to investigate if or how current news reporting on India relates to earlier stereotypical colonist representations established over centuries in literature, travel writing, or movies. Representations are considered central frameworks for making sense of the world.

Cultural productions are connected to various discourses, which are “a language or system of representation that has developed socially in order to make and circulate a coherent set of meanings about an important topic area” (Fiske, 1987, p. 11). Thus, by analyzing representations, textual critics elucidate ideological connotations that allow for a better understanding of accepted worldviews and their powerful impact.

Topic Selection

As a qualitative and interpretive methodology, textual analysis is well suited to answer questions that aim at understanding a prevalent ideology. Typical questions relate to an established media discourse and are phrased rather widely to allow for a variety of readings: How are women represented in the US television hit show *How I Met Your Mother*? What concepts of nation-state and civic belonging are negotiated in television news coverage on immigration? What idea of scientific work and scientific achievement is created in science programs for kids? What discourse on national identity is narrated on Egyptian blogs?

Questions that relate to the frequency of coverage, however, are best answered with standardized content analysis, for example: How many Latino characters are featured on prime-time television? Also, quantitative methodology can answer questions that investigate quantifiable trends in coverage, for example: How has the amount of coverage on female athletes changed over the last 30 years? When using quantitative content analysis, predefined typologies of characters need to be established in a codebook before the analysis, for example: What gender roles do female characters perform on current prime-time dramas (e.g., professional; mother; homemaker; victim; sex object). In contrast, textual analysis is suited to interrogate emerging role constellations; development of representations over time; and the connection of current representations to other current or previous discourses. For example: Are there moments of “Orientalism” in the current Western newspaper coverage on Iran? Are there differences in the representation of top female politicians compared to their male colleagues?

Cultural-critical scholars often focus on issues relating to class, race, ethnicity, and gender. Some of the connections between these issues and media content are more immediately obvious: “Orientalism” (Said, 1978) and coverage of the uprising in

Egypt; the globalization discourse on CNN International; the representations of teenage girls and women in the *Twilight* saga; discourses of neoliberalism in the coverage of the 2008 economic crisis. It can be productive for cultural scholars to investigate discourses in various types of popular media, for example, Orientalism in the US movie *Zero Dark Thirty*; the discourse of globalization in world music reviews; the representation of technology and science in the US sitcom *iCarly*; the performance of status and class in home improvement shows; the notion of citizenship in the US show 24.

Exemplar: Representing the Other in Food Reviews

The example for this chapter followed the suggestions outlined above. It uses a general question of concern to cultural scholars and interrogates it in an unusual context that is often considered fringe or trivial. The theoretical context is the question of how Others (i.e., minorities, foreigners) are represented in the media. The empirical engagement is with so-called “ethnic” food reviews.

Justification

The intention of scholarly research is to contribute to the ongoing academic discussion on a specific topic. Thus, the justification of any study has to relate to earlier scholarship. The central question for this project was “How do the media make sense of other countries, and other people?” The way we represent the Other is of central concern in a globalizing world. Major political decisions are related to the way we see other nations and the world. Classic studies on journalism employed the news values “proximity,” “elite nation” (Galtung & Ruge, 1965), and “ethnocentrism” (Gans, 1979) to explain the fact that the closer another country is (economically, culturally, or politically) the more frequent and favorable the coverage will be. More (economically or militarily) powerful nations are more likely to dominate the news flows across the world, while people and events in counties at the periphery are often misconstrued or ignored. Only extreme humanitarian crisis, natural disasters, and violent conflicts with many casualties have a chance of being covered. Leaving the limitations of news journalism behind, it makes sense to look to international media content that is not necessarily deemed relevant to an informed citizenry – more trivial and popular content. The focus on popular content relates to another tenet of cultural-critical studies: meaning is created in all forms of popular culture and there is no banal entertainment that people only use to escape the mundane.

For example, many media consumers have an idea of “what Africa is about” even if they have never set foot on African soil. This idea of Africa is the backdrop when non-Africans hear the latest news about a food crisis in Ethiopia or political unrest

in Mali. But these images in our heads have most likely developed over years of consumption of popular culture content relating to Africa through watching Hollywood movies such as *Indiana Jones*, *Tintin*, or *Out of Africa*, dancing to African music such as that of Youssou N'Dour, or enjoying animal documentaries on the Discovery Channel. Of course, personal encounters with people from the continent may play a role as do school lessons on Africa.

Another major site of cultural exchange is food. Visiting a so-called ethnic restaurant is a significant experience as it lets us encounter difference with all our senses. As media scholars, we can explore this unique cultural encounter by looking at the food reviews of ethnic restaurants. The task of food reviewers is to explain a different type of culture. Like travel journalists, food reviewers describe something “foreign” and “strange” to an audience that is normally not (yet) familiar with it.

Sampling

For textual analysis any well-established qualitative sampling methods can be used: maximum variation sampling, snowball sampling, theoretical construct sampling, critical case sampling, and even convenience sampling (for a detailed explanation see Lindlof, 1995, pp. 126–131). In any case, the sampling strategy needs to be made transparent to the reader and to be justified in relation to the research questions and theoretical concepts under investigation. For a scholarly project on ethnic food reviews, appropriate media content can be selected through qualitative sampling strategies. Following typical case sampling, for example, would mean to sample articles that capture “the typical (or normative) form of a phenomenon” (Lindlof & Taylor, 2011, p. 115.) Since in this case the phenomenon relates to food reviews on ethnic restaurants that are published in commonly accessible media, a search on Lexis/Nexis or various online news archives using a recent time frame will generate relevant articles. Sample size in qualitative research is typically considerably smaller than in quantitative research since the methodology calls for an intensive engagement with every source. The aim of typical case sampling is to generate pertinent exemplars for analysis.

One of the central tenets of qualitative research requires prolonged engagement with the participants or material under investigation, such as in a long-term participant observation in a field study. When dealing with media material it is equally important to engage in great detail with the material analyzed. Instead of just quickly focusing on the data to be analyzed, it is important to read, hear, or watch the material in context and to engage with the material in what Hall (1975, p. 15) called “the long preliminary soak.”

In the case of the food reviews, I had long been a fan of ethnic restaurants and was an avid reader of the *Boston Globe* during the time of the selection. I used my years of experience of reading the column as a starting point. While qualitative

researchers work toward avoiding apparent and avoidable sources of bias, my familiarity with the media material can be justified as providing important contextual understanding beyond the articles selected for analysis (Lincoln & Guba, 1985). Qualitative research understands the epistemological relationship between the researcher and the material to be studied as “interactive and inseparable” (Lincoln & Guba, 1985, p. 37). I used my fandom and knowledge of the articles as a first step to establish general expertise.

I have read many of these columns over the years and frequented many of the restaurants they describe. In order to gather materials for the actual analysis, I used a search on www.boston.com (a website of the *Boston Globe*) and searched for the column “cheap eats,” which I knew often covered ethnic restaurants. I deemed the decision to restrict the reviews to those of the *Boston Globe* acceptable since the journalistic style and routines of this daily newspaper are similar to those of other contemporary metropolitan newspapers in the United States. Moreover, the paper’s continuing coverage of ethnic restaurants offers access to a wide variety of articles over a significant period of time. The example described below uses a purposefully selected sample of 50 reviews. I have used these articles frequently in a class exercise to teach students the problems of media representations of the Other.¹

Analytical Strategies: Coding and Binaries

The first step of the analysis entails a close examination of all the material including an intensive and repeated reading of all articles. The second step is to code the material. There are various established methods of coding in qualitative research and discourse analysis. What all these strategies have in common is that they aim at selecting and condensing the material under investigation in a multistep process. For example, in a first round of open coding, the text critic looks for central themes or frames in the coverage.

In this first round, it can also be helpful to investigate how the articles are constructed. Besides specific genre conventions, there often is a typical formula used to produce the text. For example, the articles in this study always relied on at least two anonymous visits to the restaurant during which the reviewer seemed to have taken some company along (as a way to be able to taste various menu items). After the tasting visit, there were phone interviews with the owner or cooks. A common journalistic formula further emerged in the text itself: Authors described in a few sentence the decor of the restaurants and the people frequenting it. They often positively acknowledged the presence of what they considered “ethnic” customers in the restaurant. Moreover, owners tended to be quoted on how they related to the food served, for example, whether they were from the featured country and whether they had learned cooking from someone in the home country. There were often comments on the speed, attitude, and friendliness of the service staff. The

main part of the on average 1000 word reviews then dealt in some detail with specific dishes.

In the third step of analysis, these broader observations were further narrowed to specific textual elements. To reach deeper into the materials, some standard questions of cultural-critical textual analysis (see Barker, 2000; Vande Berg, Wenner, & Gronbeck, 1998) were adapted for the study: Are there patterns of binary oppositions in the text, such as “us” versus “them”? What in the text is considered normal, common sense, enjoyable? What verbal or visual metaphors are used? Whose voices are heard, and who is silenced? Who is established as ideal or preferred reader?

The overall research question for this project was: How do the reviewers create and produce national distinction and culture? It quickly became clear, however, that other stakeholders – the restaurant owners and workers – were also implicated in this discourse, leading me to ask further: How do restaurant owners and service staff produce national distinction? Upon close engagement with the text I found that the intrinsic goal of both parties (reviewers and restaurant owners/workers) in these reviews was to work on a discourse that emphasizes difference. This discourse was driven by the genre itself. What is the point of frequenting and reviewing an ethnic restaurant if it is not different from any “regular” bar at the corner?

As a next analytical level, I used a typical strategy of deconstruction by establishing discursive binaries in the text (see Fiske, 1984; McKee, 2003). These binaries are related to the topic and earlier scholarly research on representing the Other. Since the coverage is a type of international (even as it is local) reporting, the binary of “us” versus “them” is central. Cultural theory helped to establish “authentic” versus “inauthentic” as a further binary. I used these initial binaries to search for text passages that exemplify these distinctions. As a next step, I aligned other passages according to the us/them dichotomy. All that was considered part of the ethnic restaurant experience was listed to the left. To the right are the opposite side of the binaries that may or may not be explicitly mentioned in the text. Often, this side is the silenced and unquestioned common sense position.

Establishing these binaries throughout the texts augments the analysis in multiple ways. First, it allows the critic to further condense the material and filter out important textual elements. The binary starts with the binary “us” versus “them,” which is typical for reporting about Others. The elements that are mentioned in the left column of the binary list are those attributes of the reviews that are positively sanctioned, even if not all restaurants reach the established goal. Thus, the fact that a review criticizes a restaurant decoration for not being typically “Thai” or a cook who is not from the home country reinforces the established common sense position of an ethnic restaurant “as it should be.”

In this binary list, it becomes discernible that the restaurants are pressed into a certain ideal that rewards a homey, cozy, and laid-back atmosphere, and business models where the standards of contemporary, commodified, organized business strategies don’t apply. A long quote at the beginning of a review of a Middle Eastern restaurant exemplifies the basic binary structure:

Most of us like restaurants personable. We like to feel that real people have put their souls, as well as their work, into the food we're going to eat. We're intrigued by ambience and surroundings that show an individual's taste – not some corporate purchasing department. (Arnett, 2003)

Other textual examples further illustrate this point: The owners of the restaurant 9Tastes chose the name “because nine is a lucky number,” and not because of branding or marketing considerations (Subramaniam, 2003). Instead of professional and skilled training, the reviews emphasized family tradition and connection as, for example, in this description of Greek cooks noting that “Guiding their cooking was a mix of their mother’s recipes and those of a 80-year-old Greek cook who trained them” (Taylor, 2002). Another review similarly described a Thai couple who

became restaurateurs serendipitously. The family emigrated from Bangkok 20 years ago and almost immediately went to work at Montien, which a Chinese family owned. Tony cooked and Pam did just about everything else – waited tables, tended bar, hosted. When the family decided to get out of the restaurant business 10 years ago, they offered to sell Montien to the Sukthevas. (Kowalczyk, 2003)

The idea of noncommodified relations extends to the clientele who is not supposed to be treated as paying customers but as guests and friends: “When [the meze] came, we felt like revered guests in a Turkish home (only with plastic forks)” (Taylor, 2006). Another Greek restaurant is

a place where members of the Greek community can go to see one another, wave across tables, and socialize in a way that people did many years ago – and still do in small towns. The hostess seems to know most of the older women and treats them almost reverentially. (Julian, 2001b)

This statement also taps into another typical nostalgic discourse that favors “many years ago” and “small towns.” A Mexican restaurant “is where transplants from Mexico come to get their fix. This colorful family-style restaurant, called a fonda in Mexico, is where you’ll find such delicacies as cuitlacoche” (“Most authentic restaurants,” 2005).

Second, another important aspect of a binary list is that it allows the critic to evaluate what is left out in the text, what the unquestioned or unmentioned default position is. Note that various attributes of “them” are verbalized in the reviews, while the “us” remains silenced. These unspoken elements (noted in parentheses in Table 15.1) are the assumed position of the “us”: It is in this right-hand column that the accepted common sense position becomes visible. These elements cannot necessarily be illustrated with verbatim “manifest” statements in the media content. But by filling in the missing binary, the critic is able to explain the cultural assumptions of the common sense and dominant position.

Table 15.1 Textual binaries in ethnic food reviews

“Them”	“Us”
Restaurant owner and family, staff	Reviewer, readers
Authentic	(Inauthentic)
Typical, essential, genuine	(Indistinguishable, hybrid)
Based on national distinction	
Family, community	(Individualized, alienated)
Ethnic guests as friendly community	
Friendly staff who makes guests feel at home	
History/roots	(Future orientation, without roots)
Recipes, food based on long traditions	
Static	Flexible
Slow	(Fast)
Service, food	
Cozy, warm	Hectic, cold
Inside the restaurant	Street (life) outside the restaurant
Self-organized, family-run	(Organized, bureaucratic, corporate)
Cooks and owners not trained professionals but skilled through family connections	
Noncommercialized relations	(Commodification)
Customers as guests, friends	

Establishing a Theoretical Context

To further delve into the common sense position of the text, the next step is to contextualize the text in relationship to other scholarly concepts. After condensing and systematizing the material through several levels of coding, it is important to connect the data under investigation to the earlier established research questions and tie the material to appropriate theoretical frameworks. The goal of qualitative research is “to make contextually grounded, theoretical points that are viewed as a contribution by the relevant professional community of readers” (Golden-Biddle & Locke, 1997, p. xv). Following the principles of grounded theory, the critic moves from the data to theoretical explanations that are constantly re-evaluated in a continued engagement with the media content. A textual analysis ultimately has to present one or multiple readings or interpretations that explain the cultural and ideological assumptions at the core of the text.

Media and National Identity

The analysis of the text examined here revealed several strategies used to establish a restaurant as “genuine” or “authentic.” This “authenticity check” was conducted

throughout the materials. Words such as “ethnic,” “authentic,” “traditional,” “exotic,” and “genuine” were all used to designate a cultural distinction and categorization and to establish the ethnic/national credentials of the different restaurants.

In the opening paragraphs, reviewers typically established a clear cultural categorization by highlighting the decor. As a reviewer commented lightheartedly: “Themis manages the storefront restaurant, which counters its environs with bright wood panels and sunny murals of Greece (must Greek restaurants so cruelly flaunt their homeland’s azure waters and sun-bleached patios?)” (Taylor, 2002). On the other hand, it was deemed a problem if “while you nibble Japanese and Korean specialties, putti, the little Italian angels, smile down from the canvases on the ceiling” (Julian, 1998).

Reviewers further authenticated the restaurant by educating their readers on unusual food while simultaneously establishing their own authority. As one review put it, “in a Korean restaurant, one authenticity test is the panchan, or little side dishes that come with the meal” (“Most authentic restaurants,” 2005).

Another striking similarity across all reviews by various authors is the fact that they often described the owner and the owner’s family or other staff – especially the chef – and the details of the restaurant’s founding or the cooking expertise. These descriptions were another “authenticity check.” For examples, a review of a Thai restaurant opened with the detailed names of the owners signifying exotic complexity:

Six year ago, Suriyant “Toy” Jamdee and his friend Suraphong “Tu” Pinyochon opened Brown Sugar Café in the Fenway. Pinyochon’s wife, Darny, greets customers. Within view of the ballpark lights, the little place has a graciousness that is unusual. (Julian, 2002a)

Similar qualifications related to the restaurants’ customers. The ethnic makeup of their clientele was carefully noted – “I was pleased to note that we were the only non-Asian clientele on our first visit, taking it as evidence that this Vietnamese is serving the genuine article and not just catering to the South Lawrence tourist trade” (MacDonald, 1998) – with the presence of American costumers viewed with suspicion. The staff was marked for their difference as well: “The staff at Viet Cafe has an engagingly tentative air, sweet but seemingly fearful of being spoken to roughly. You feel you ought to keep your voice low as not to startle them, quite unlike the brash Boston wait staffs” (Arnett, 2000).

Of note is the fact that the descriptions of exoticism and authenticity were done from the perspective of an unquestioned default. The reviewers brought in a specific understanding of what a Thai, Chinese, Vietnamese, or Turkish restaurant has to look like. Mainly this default was based on the experience with other restaurants of the same category, not actual visits to that country. Often, reviewers established a contrast between the exterior (the cold or hectic city of Boston) and interior of the restaurant (warm and/or calm):

It's cold and dark out these late fall nights, but when you walk into Merengue, you feel as if you've landed in a tropical spot. The walls are green, and there's a faux facade of a cottage, its shingles bright and blue. Over the bar is a mural of parrots and bright flowers. (English, 2003)

In another review "the orange walls inside Bhindi Bazar seemed to radiate warmth, just what we needed after braving the blustery cold" (Subramaniam, 2002b). There was an even more nostalgic tone in this review:

The hustle and bustle of Boylston Street seemed far away in this basement restaurant across from the Prudential Center. Time was on hold in Delhi Bistro as we relaxed to the melodious sounds of flute and tabla playing in the background. A soft-spoken waiter asked us whether we preferred mild, medium, or spicy dishes, and waited patiently as we decided. (Subramaniam, 2002a)

When reading the reviews, it becomes clear that reviewers and owners engaged in different cultural strategies for establishing authenticity and national difference. For the reviewers, it was important to establish the dissimilarity of these restaurants following the standards of the genre of ethnic food reviews. Difference became a mark of quality. Restaurants that played too obviously to local US tastes were seen as a problem: "The menu is slightly upscaled [*sic*], too, and recognizes that the dining public can embrace ethnic cuisine on its own merits with no Americanization" (Arnett, 1998b). Another reviewer commented: "I liked the fact that when one asked for spicy here, the dish was prepared that way, no toning down just because the diner's not Korean" (Arnett, 1998c).

Restaurants were defined and categorized along national distinctions that relied on clear, often static, and essentialized cultural definitions. These distinctions inscribed accepted center-periphery power relationships. Indeed, what makes a restaurant an ethnic restaurant? The term "ethnic" often stands in for "Third World" or periphery – a French restaurant would not be called an ethnic restaurant. Interestingly enough, in this particular case, Turkish and Greek restaurants (as countries at the periphery of Europe), and even Japanese restaurants, were also included in this category.

Yet it would be naive to regard this categorization as a one-way process. Instead, the statements of owners demonstrate that they too engage in the performance of authenticity by striving to create an "authentic" national identity to be sold to customers. As an owner quoted in one of the reviews put it, "We are not competing with the kebabs made at other restaurants made in town . . . We are competing with the kebabs made in Turkey. We want to be as good as in Turkey or better" (Taylor, 2006).

The restaurant owners negotiated a position that allowed for enough national difference – as a marketable brand distinction – while always making the effort to guide potential clients through familiar categories into new territory, for example, by describing a dish on the menu as "Vietnamese pancake" or naming a restaurant

“Beijing.” Possibly negative political meanings were excluded or sanitized, for example, by calling a cuisine “Persian” instead of “Iranian.” National identity had to be established as different enough to be considered special in a crowded restaurant market, yet still able to connect to US expectations so as to not drive away customers not ready for an experience that was too “exotic.” One reviewer spelled out this ambivalent strategy in detail. She praised a Cambodian chef: “Her flavors are distinctive, and there’s no Americanization of the food. Yet the cuisine is easy to understand: there’s no feeling that you’ll never know what you’re eating or never get the stuff saved for insiders” (Arnett, 1998a). For the restaurant owners, national identity became a branding strategy that positioned a unique dining experience as a competitive advantage.

Both sides engaged in a discourse of authentication and distinction. In this process national identity was negotiated (by the reviewer) and performed (by the owner and staff). This performance was grounded in a discourse of national identity or the “idea that people and things from and within national borders possess very particular, idiosyncratic, national characteristics” (Du Gay et al., 1997, p. 48). As a cultural strategy to make sense of one’s own identity and that of others, it may seem harmless enough, but here is where the cultural-critical commitment to interrogating power relations is important. These food reviews are but one example of how media negotiate and represent the nation-state.

Thus, it is helpful to draw here on scholarship on the relationship between media and the nation-state that has emphasized that both are intrinsically intertwined (e.g., Waisbord, 2004). First newspapers (Anderson, 1991), and later news magazines and national television news (Gans, 1979), have played a distinctive role in defining, explaining, and representing the nation-state for audiences. Anderson’s idea of the nation-state as an “imagined community” explains the centrality of representations for the existence of the nation-state system (1991, pp. 6–7):

[The nation] is *imagined* because even the members of the smallest nation will never know most of their fellow members, meet them, or even hear of them, yet in the minds of each lives the image of their communion . . . it is imagined as a *community* because regardless of the actual inequality and exploitation that may prevail in each, the nation is always conceived as a deep, horizontal comradeship.

In this study, the reviewers often presented a geopolitically fixed situation defined by national borders. The current political status quo was reinforced along with traditional political center–periphery thinking.

The Concept of Culture: Static versus Dynamic

These restaurants were scarcely given a chance for creative development. Attempts to present hybrid food and new preparations were rarely acknowledged and mainly

criticized. For example, an Indian restaurant was condemned for a new type of bread filling: “Chicken and pesto? What is going on here? The Kebab Factory has woven some unlikely combinations into its repertoire of traditional Indian fare. But they haven’t neglected the classics” (Julian, 2001a). Faced with a large choice of seemingly out-of-place dishes, the reviewer ended the article almost philosophically:

Am I old-fashioned, passing the pesto in favor of the poori, brushing past pizza to taste the pakoras? The younger generation of Indians is very excited by his food, [the owner] tells me. I am, too. And we’ve probably eaten completely different meals. (Julian, 2001a)

The restaurant remained authentic only because it held onto a traditional menu. In an earlier review, a new Asian restaurant was advised that “sticking to the Korean basics would seem to be a good first plan” (Arnett, 1998c).

As in a museum, these cuisines were frozen in time – national culinary distinctiveness was framed within contemporary (often short-term) political borders. This discursive strategy neglected, especially, food preparations developed in regional or local spaces or through centuries of cross-border influences, such as along the spice road. Food was not understood as an active and transitory cultural expression but was preserved as an essentialized category. Moments of hybridity and new development were often negatively sanctioned, as they would call for an understanding of culture as a dynamic, continuously changing process. However, it should be noted that the reviews used here (from the late 1990s to 2006) reflect a certain stage in restaurant development in Boston. The later the reviews were issued, the more likely reviewers engaged positively with hybrid forms of cooking, which became more fashionable.

Othering: Us versus Them

A further step in connecting the material to other theoretical explanations is to continue to engage in the binary setup. A central motivation of the study was to see if seemingly trivial journalism could be used to understand the media’s approach to representing the Other. The question now is how exactly the texts create an idea of an Other. By continuing the binary setup along the dimensions of the Other and filling in the mostly unspoken counterparts for the United States, the preferred reader and underlying cultural preferences become visible. As is typical in media representations of Others, the media text often reveals more about the unspoken ideological assumptions of the “we” than the lived reality of the Other.

In the case of the food reviews, the articles depended on a clear demarcation against an ethnic and exotic Other who tended to be a first-generation immigrant from so-called Third World or periphery countries. It speaks for the text that despite the limited length of the articles, owners are often quoted verbatim and not – as is

Table 15.2 Extension of binaries

Other	We
Ethnic/often non-White/periphery/ first-generation, immigrant Spoken about	(US American, nonethnic, probably White, no direct migration background) Spoken to = Preferred reader

a typical problem for international reporting – silenced or replaced by expert voices from Western elites. But as the fixed voices in the formulaic reviews, the restaurant owners were, nevertheless, “put in place.” Beyond national difference, ethnic difference was established, too. For example, in one case, even African Americans belonged to the Other. The default “us” is White:

The 90-seat Roxbury storefront holds a rainbow of customers, too: on a recent Saturday night, there were Latinos, African-Americans and a few Caucasians. At the table next to ours were three generations of African-Americans, from baby to grandmother. People come for the *mélange* of flavors and scents that emanate from the kitchen. (English, 2003)

The preferred reader established in these articles is US American, nonethnicized, probably White, without a direct migration background. This dichotomy continues to enforce, or at least does not challenge, a national identity that minimizes the US historic experience of continuous immigration and mobility. US identity is endowed on a population that is a static, egalitarian, nonracial assembly while migrants and minorities are Others with regard to race/ethnicity and class.

Further Interpretations

As a last step of the analysis, the researcher has to take the discursive strategies that were established earlier and the elements that were tied to a wider theoretical framework through to another round of interpretations. The goal is to establish various comprehensive readings of the text. These interpretations should probe the question as to why the examined texts “work” at the given time. How do the articles relate to established ideologies and structures of feeling?

In this case, the binary structure again helps to approach another dimension of interpretation. If one reads along the two columns, one is struck by how the attributes of the two sides position “them” in a reality that is sensual, emotional, dependent on kinship relations, and driven by noncommodified attitudes. This world provides

a welcome and appreciated escape for “us” – the reviewers and the preferred readers – who are nonethnicized Americans. “We” seem to be living in a “cold” world of structure, commodity production, and Fordist principles. Despite the fact that the reviewers exoticize the Other in positive terms and engage in an accepting, tolerant framing, this binary leaves rationality on the side of the reviewer. The world of the ethnic restaurants is in the realm of the emotional and irrational. Visiting the restaurants is a sensual encounter that does not necessitate cerebral engagement. A reviewer writes about a Cambodian restaurant: “The herbal scents of lemongrass; the bite of chilies; smoky, sultry accents; a hint of sour and then sweet – all these tastes and smells converge, beguiling the senses. Falling in love was never easier” (Arnett, 1998a).

This dichotomy is amplified by the discursive strategy that positions ethnic food and owners in the past. To make this point, a reviewer starts her review of a Palestinian restaurant with a daring historic account:

A kebab is one of the simplest, most appealing dishes. In fact, you might say that humans have been eating food this way since they first started cooking. Meat would be skewered and roasted whole over open fire, then cut up and eaten in pieces. Later the meat was cut before it was cooked. So the kebab we know today is a refinement of a tradition practiced for centuries, and still eaten all over the Middle East. (Julian, 2002b)

Her quasi-scientific account of “humans [who] have been eating food this way since they first started cooking” connects not only the restaurant but also a whole region to premodern times. This quote is indicative of the overall discourse. Most of these articles echoed a cultural sensibility that positions the premodern Other against a modern “us.” Moreover, this premodern state was connected to irrationality and positioned against modern rationality. As Table 15.3 demonstrates, sensual and emotional language was typically used to describe the food, the decor or the cooks’ genealogies. Restaurants were considered successful if they employed methods that are counter to the rational, organizational model of advanced capitalism. The reviewers followed the genre conventions by using clear judgmental language and a didactic approach toward the reader. This journalistic style reflects the enlightenment spirit

Table 15.3 Cultural sensibility and ideology of food reviews

Not rational	Rational
Attitudes of cooks towards food	Professional attitudes of judgment
Descriptions of food and decor in emotional, sensual terms	Didactic voice of reviewers
Cultural sensibility/ideology	(Cerebral, rational)
Sensual, irrational	Modern
Premodern	Now
Then	

of modernity. The possibility of hybridity – as a postmodern sensibility – is left out or regarded negatively in these articles.

There are several possible interpretations of this discourse. One can understand this text and its sustained desire for authenticity as a type of symbolic and cultural resistance to a world where traditionally firm categories such as nation and national culture have become fluid. This idea links to the anthropological insight that food production and consumption have always been used to create a sense of identity and to maintain boundaries. In this study, these reviews negotiate new boundaries in a specific geopolitical moment characterized by commodification and globalization. However, the tendency to frame this exchange in a premodern/modern dichotomy falls prey to a problem explained by anthropologist Fabian (1983). The reviews represent the Other in an earlier time, running the risk of depicting contemporaries as primitive ancestors caught in static, temporal displacement. The ideology of the food reviews dehumanizes Others by using them in a nostalgic enactment that reinforces outdated power relationships.

Yet another cultural interpretation or reading could explain the commodification and branding of national identity and the performance of ethnic difference that the reviewers and restaurant owners engage in as an ironic and self-aware commentary to make sense of a world in flux. The discourse surrounding the ethnic restaurants becomes a site where civic and cultural identities are negotiated. After all, these reviews have been written at a time when globalization has become an experienced cultural and economic reality even in the powerful centers in the West – and not something that only happens to Others.

There is a need for new research to carefully position such analyzed texts in their historic and geopolitical context. Further studies could analyze ethnic reviews in a wider set of media and over a longer period of time. This strategy would enable textual analysts to understand shifting ideologies over time regarding globalization, the demise of the nation-state, and cultural identity. At any rate, the textual analysis of selected food reviews presented here demonstrates how popular journalism negotiates cultural sensibilities and ideologies about how we see the world. This type of method took the analysis of media coverage, that is, various themes of the coverage or specific frames in these articles, only as a starting point. The central contribution of textual analysis is its interpretation beyond the manifest content. Its aim is to explicate the prevailing ideologies and power relations that allowed this content to be produced in the first place.

NOTE

Cultural History and Media Studies

Richard K. Popp

ABSTRACT

Understanding meaning making and its capacities to shape social experience is difficult enough in the present. Yet interpretation poses particularly thorny questions when researchers are interested in describing social worlds and patterns of thought that years ago dissipated into the past. Historians have argued fiercely about these challenges and scholars in media studies stand to benefit from eavesdropping on these historiographical debates. For one, they can help us clarify our conceptions of media and culture. And second, they offer insight into how theories of culture can be translated into historical projects. Taking readers through the primary ways that culture has been operationalized in recent historiography, sections examine symbolic anthropology, critical theory, cultural studies, discourse, identity, and recent calls for a more cultural materialist approach. The chapter closes by examining a number of cultural materialist frameworks that might be especially useful to media scholars.

Media studies' interdisciplinary nature has meant that it has borrowed liberally from fields across academia, pocketing a useful theory here or a helpful methodology there. In this way, the field can be seen as almost a direct outgrowth of the "genre mixing" (Geertz, 1983, p. 19) that reshaped academic study in the closing decades of the twentieth century. Various called the "cultural turn," the "linguistic turn," and the "interpretive turn," this development placed the humanities in the role of lender

and the social sciences in that of borrower, reversing the trade flow of concepts that had characterized social research in the mid-twentieth century. "The instruments of reasoning are changing," anthropologist Clifford Geertz wrote in 1983, "and society is less and less represented as an elaborate machine or a quasi-organism and more as a serious game, a sidewalk drama, or a behavioral text" (p. 23). In media scholarship, these currents made themselves most apparent in the growing profile of researchers working within the frameworks of cultural studies, critical theory, political economy, and qualitative sociology between the 1970s and 1990s. In this regard, James Carey's 1975 call for a "cultural approach to communication" and Todd Gitlin's 1978 reimagining of the field as helmed by C. Wright Mills instead of Paul Lazarsfeld can be read as prophetic of changes just over the horizon, as media studies shifted its footing from a field dominated by questions of behavior to one largely concerned with questions of culture (Carey, 1992; Gitlin, 1978).

Similar changes were afoot in academic history too, as the study of cultural institutions gained wider acceptance and more traditional areas of inquiry – politics, diplomacy, business, labor, technology, African American history, and women's history – came to look more like culture. The "new cultural history," as it was eventually dubbed, represented a shift in both orientation and method (Hunt, 1989). Whether one was studying Hollywood studios or plantation slavery, the innovative thing to do was to treat that subject matter as culture in need of interpretation (Darnton, 1980; Hunt, 1989). Thus the new cultural history assigned itself many of the same interpretive challenges as media studies, only directed at the past.

This essay draws on historiographic debates within the US academy in the fields of history, American studies, and historical sociology, tracking the cultural turn and the subsequent twists it has taken over the past four decades. Historiography deals with how historical research is conceptualized, planned out, and executed. It provides a kind of scaffolding that helps to organize the aims of a researcher, the theoretical perspectives she or he will bring to bear on a topic, the scope and scale of their study, and the way their work will engage with ongoing debates. Historiography, then, is what makes it possible to take an enormous area, such as the history of television, and narrow it down to a researchable topic, such as the gender norms of television viewing in 1950s suburbia or the work culture of African American screenwriters in 1970s Los Angeles. Ironically, this process has the effect of both narrowing and expanding the scope of study. Our two examples no longer aspire to tell us the story of television in its entirety, but they do tell us part of that story in great detail. And just as importantly, they open outward to write new chapters in the histories of gender, race, domestic life, suburbia, urban life, creative work, and other areas. Different historiographies generate different questions; they point to different archives; and they provide different frameworks for sorting out and presenting one's findings. As we will see, they also provide different ways to think about culture.

Understanding meaning making and its capacities to shape society is difficult enough in the present. Yet interpretation poses particularly thorny questions in historiography because researchers are interested in describing social worlds and

patterns of thought that have dissipated into the past (Douglas, 2008). Historians have written extensively about the challenges involved in recovering the complexities of culture. Media studies scholars stand to benefit from eavesdropping on these conversations. Doing so can help us clarify our conceptions of culture and in the process hone our interpretive methodologies. Moreover, these debates offer cues and insights into how theories of culture can be translated into historical projects that help us better understand the many ways in which media have fit into social experience.

This chapter is structured to take the reader, in roughly chronological fashion, through the primary ways that culture has been defined and treated as an area of historical inquiry since the start of the cultural turn. The debates it explores occurred largely, although not entirely, among scholars based in the United States, though in many cases their areas of study were international and much of the theory they enlisted was European in origin. Sections examine symbolic anthropology, critical cultural theory, cultural studies, discourse and identity, and recent calls for a more avowedly sociocultural history that focuses on the interplay of semiotic systems and large-scale social structures. The essay closes by exploring three historiographic frameworks that lend themselves well to a cultural materialist approach – the culture industry revisited, the history of the senses, and the history of the book. Throughout the essay, I highlight studies that exemplify how different conceptions of culture have been put into action. The examples chosen are studies that have been influential in their fields and explore some facet of media culture.

Turn 1: Symbolic Anthropology and Folklore Studies

To understand how historians have dealt with interpretation, it is helpful to understand how questions of semiotics, hegemony, discourse, identity, and cultural practice became central concerns in the first place. In one way or another, the study of culture – in the anthropological “whole way of life” sense – attracted attention for much of the twentieth century. In the 1930s scholars began to look at popular texts as legitimate sources that might offer a window into everyday life; in the postwar years, the “myth and symbol” school of American studies produced sophisticated works on the place of iconography in historical change; meanwhile, a branch of the Annales School in France turned their attention to *mentalités*, or patterns of thought; and at roughly the same time, British investigations into ordinary life and working-class expression began to coalesce into the new field of cultural studies (Cook & Glickman, 2008).

Notwithstanding these important predecessors, it was the impasse felt by historians in the 1970s as they struggled to overcome the limitations posed by the tools of contemporary historiography that sparked a turn toward cultural theory and in ret-

respect signaled the beginning of a coherent subfield. At the time, the motor of innovation in historical methodology was the “new social history” and involved appropriating the tools of quantitative social science. The aim was to translate administrative records and other quantifiable documents, such as census reports and tax records, into large pools of data that shed light on populations who otherwise left little mark on the historical record. In time, these studies could be combined into sweeping insights into the workings of broad-scale social transformation. Yet even the new social history’s wider lens on the past seemed to obscure as much as it revealed. As William Sewell (2005, p. 40), then a young social historian, recalled of the time:

It seemed to me that although quantitative methodology had enabled us to understand more and more about the structural constraints and social forces that shaped people’s lives, it offered no guidance for understanding how people actually made sense of and grappled with these forces and constraints – that is, for how they actually made history.

For Sewell and a handful of others, anthropology, which at the time was still oriented toward mapping the logics of non-Western cultures, looked as though it might offer the same possibilities for peoples of the past.

Clifford Geertz’s work in symbolic anthropology had a profound influence on this development. His 1973 essay collection, *The Interpretation of Cultures*, attracted droves of admirers and, just as crucially, Geertz worked closely with a number of young historians, including Sewell and Robert Darnton, at Princeton University’s Institute for Advanced Research. Historians were attracted to Geertz for the same reasons that communication scholars like Carey were: his essays provided a means of thinking about culture as not just an aspect of social life, but as the interpretive capacities that made human experience and social organization possible in the first place. “Undirected by culture patterns – organized systems of significant symbols,” Geertz (1973, p. 46) argued, “man’s behavior would be virtually ungovernable, a mere chaos of pointless acts and exploding emotions, his experience virtually shapeless.” Culture, the “accumulated totality” (p. 46) of semiotic communication in a society, provided the lens through which the physical world was refracted as social reality. Thus acts of communication – utterances, stories, rituals, and so on – were strands within “webs of significance” (p. 5) that made raw experience readable. Recovering the insider’s view, or the “subjective meaning of action” (Weber, 1968, p. 9) – which Geertz characterized as the capacity not only to distinguish the intentionality behind a wink from the involuntary spasm behind a twitch, but to tell a flirtatious wink from a mocking wink and a mocking wink from a parodied wink, and so on – was the task of cultural analysis; the analyst’s method, “thick description,” was to dig through layer upon layer of context.

For historians, Geertz’s theories meant that popular expression and public ritual could be read as a text with an internal cohesion that in turn revealed underlying patterns of thought (Walters, 1980). Historians did not rely on Geertz alone. Other

anthropologists – Victor Turner, Keith Basso, and Mary Douglas – were also influential, offering ways to think about rites of passage, jokes, and boundaries (Darnton, 1986). Folklore studies showed itself useful too. Again, the task was to treat genres of popular representation as a larger sense-making system. Even the popular culture of modern societies, historian Lawrence Levine (1992) argued, could be analyzed as folklore. Movies, hit songs, novels, and other mass culture texts may not convey the same sense of folk authenticity as pre-industrial forms, he acknowledged, but they could nevertheless act as arenas “in which many essential things are realized: lessons are learned, values enunciated and repeated, modes of behavior scrutinized, social institutions and their effects explored, fantasies indulged” (Levine, 1992, p. 1392). In other words, popular texts could be treated as not only imperfect representations of reality, but also representations *for* reality – or symbolic resources audiences used to interpret social life.

Thus whether Geertz’s name was invoked or not, his call for thick description, or the notion that the telling detail could be unpacked to reveal a whole universe of symbolic logic, was central to the interpretive turn in history. Indeed, some of the most influential early examples of the cultural turn revolved around singular incidents (Davis, 1983; Ginzburg, 1980). Robert Darnton’s *The Great Cat Massacre and Other Episodes in French Cultural History* (1984) might be the purest example of Geertzian anthropology applied to historical inquiry. Having first made his name in intellectual history and the social history of the book trade in Enlightenment France, Darnton’s exposure to anthropology turned him into an advocate of “history in the ethnographic grain” (1984, p. 3). Darnton framed his approach as a kind of democratized intellectual history, explaining:

Where the historian of ideas traces the filiation of formal thought from philosopher to philosopher, the ethnographic historian studies the way ordinary people made sense of the world. He attempts to uncover their cosmology, to show how they organized reality in their minds and expressed it in their behavior. (p. 3)

But how does one enter into the minds of individuals who lived centuries ago and left little to no direct evidence of their thoughts in correspondence, diaries, and other traditional sources? The answer was to examine what they thought *with*: narratives, rituals, and symbols. All could be scrutinized for what they meant at the time through an ongoing process of deep contextualization, “passing from text to context and back again until [the historian] has cleared a way through a foreign mental world” (p. 6). In charting this landscape, Darnton saw great value in the unusual because it forced the historian to directly confront the utter “otherness” of the past. In a Geertzian sense, the initially inscrutable episode or detail “winked” at the historian. “When we cannot get a proverb, or a joke, or a ritual, or a poem,” Darnton explained, “we know we are on to something. By picking at the document where it is most opaque, we may be able to unravel an alien system of meaning” (p. 5).

Darnton's "wink" was a particularly grisly piece of working-class folklore from the print shops of eighteenth-century Paris – the story of a pair of apprentices who, seething with resentment toward a cruel master and mistress, pulled off an elaborate ruse to ceremoniously slay their cats. Layer by layer, Darnton unpacked the story, revealing the printing trade's deteriorating labor conditions and rough and tumble work culture, the wanton animal abuse that characterized merrymaking at the time, and the occult sexuality that swirled around the symbol of the cat in old regime France. Context in place, Darnton showed how the massacre and its ritual retelling was understood by its perpetrators as an act of defiance, allowing them to humiliate their employer, but in a manner that was enigmatic enough to get away with. Darnton's choice of a disturbing event was intentional. Although the book was an essay collection, it took its title from the chapter that was most likely to induce a feeling of "culture shock" (1984, p. 4). As Darnton saw it, the cringe readers felt forced them to acknowledge the distance between themselves and people of the past. Such an understanding of history brought the contingency of culture into sharp relief because it showed that everyday life has accommodated an astonishing array of mental landscapes.

The turn toward symbolic anthropology was not without its detractors. For the traditional minded and diehard social historians, the cultural turn represented something of a detour into triviality. But even sympathetic observers saw real shortcomings in the new ethnographic history. Some suggested that by turning everything into culture, scholars left themselves vulnerable to missing those moments when major shifts in cultural practice were themselves a driving engine of change (Biernacki, 1999). More often, though, symbolic anthropology was criticized as ill equipped for explaining structural social power (Nord, 1988). One problem with the Geertzian approach, critics held, was that it was overly synchronous, or focused on isolated moments. The simple mechanics of thick description, which involved freezing time in order to draw connections between various cultural elements – for instance, tomlcats and apprenticeships – diverted attention from diachronic change, or change in time; thus the historian lost sight of large-scale shifts in social power that don't take place within the temporal framework of the moment, but in the much longer sweep of time as it unfolds across years, decades, or even centuries (Sewell, 2005).

Turn 2: The Culture Industry, Hegemony, and Cultural Studies

Historians most concerned with questions of power had other camps to raid. Specifically, they drew on Western Marxism and gravitated toward notions of ideology and hegemony. These ideas were in some cases more than a half-century old, but they nonetheless represented fresh thinking in the 1970s. Gramsci (1971), who penned his

thoughts as a political prisoner in Fascist Italy, had been almost unknown in the English-speaking world before a few Marxist historians began to champion his writings in the 1960s (Eley, 2005). The Frankfurt School's critical sociology was better known to postwar social scientists, but much of the school's earlier work in cultural criticism, written between the 1920s and 1940s, had been little read. Around 1970, both sets of ideas began to reach larger audiences when English translations of key works appeared in wide release for the first time. In addition, a number of influential historical studies, such as Eugene Genovese's (1974) work on hegemony in US slavery, appeared at roughly the same time, demonstrating the remarkably original forms of analysis such frameworks could yield.

Again, historians were drawn toward critical theory for many of the same reasons that media scholars were. In Gramsci's case, hegemony provided a whole new set of questions to ask about the interplay of culture and power. "To resort to the concept of cultural hegemony," Jackson Lears (1985, p. 572) observed, "is to take a banal question – 'who has power' – and deepen it at both ends." Driving this expansion was a number of key observations about how power worked in relation to culture in modern democratic societies: that subordination is more often secured through legitimation and acquiescence than strong-arm tactics; that the social alliances, or "historical blocs," that safeguard the *status quo* often cut across class lines; that the reproduction of common sense parameters of thought, or "spontaneous philosophies," is also the reproduction of economic power; and that subordination is never inevitable, total, or complete, but rather an ongoing and unstable process. True to his Marxist background, Gramsci maintained that power was ultimately used to maintain the primacy of capitalism; but in an important departure from Marxist orthodoxy, he saw that power radiating from popular experience in ways that critical scholars had previously ignored.

Hegemony, then, offered historians a framework that both foregrounded issues of social inequality and granted formidable clout to the symbolic. In this regard, it was sometimes promoted as a corrective to Geertzian methods. As Lears (1985, p. 573) explained: "People indeed create their own symbolic universes . . . But a given symbolic universe, if it becomes hegemonic, can serve the interest of some groups better than others." Broadly put, a hegemonic approach was less concerned with recreating the inherent logic that governed bygone patterns of thought than in locating the areas of cultural life that at once accommodated desires for moments of autonomy and pleasure and reaffirmed structures of social inequality. Such an endeavor meant looking for the "cut-off," as E. P. Thompson (1977) put it, or the point at which symbolic acts of dissent ultimately fizzled out. "The villager is wise within his own village," Thompson (1977, p. 265) explained, "but accepts the inevitable organization of the outer world in the terms of the ruler's hegemony: he bitterly resents the exactions of the landowner and the moneylender but continues to believe in a just king or righteous Tsar." That "cut-off" might take the shape of a charismatic ideology or it could be located within key cultural institutions – the church, schools, media, the marketplace, or other sites. In any case, the researcher's

field of vision was refocused from culture in general to the engine rooms of ideology.

The Frankfurt School's critical framework lent itself well to this approach because it offered a means of understanding culture as both a situated mode of sense making *and* as the product of an industrialized news, entertainment, and marketing apparatus. According to this perspective, there were real implications to the fact that mass media texts were the end products of bureaucratic, systematized, and formulaic production processes. For Horkheimer and Adorno (1972), the great significance was that, as a form, mass culture ultimately expressed and executed the will to control that infused all forms of modern social organization. "All are free to dance and enjoy themselves . . .," they wryly observed. "But freedom to choose an ideology – since ideology always reflects economic coercion – everywhere proves to be freedom to choose what is always the same" (pp. 166–167). Most insidious, from their perspective, was the tendency of mass culture to fetishize everyday forms of domination. "Donald Duck in the cartoons and the unfortunate in real life get their thrashing so that the audience can learn to take their own punishment" (p. 138). Such broadsides on mass entertainment later earned them the scorn of a generation of scholars more sympathetic to popular tastes. Yet those who looked beyond the Frankfurt School's narrow prescriptions of taste saw undeniable value in its central assertion that, as Lears (1992, p. 1420) put it, there were "interconnections between the apparently dissimilar realms of mass entertainment and instrumental rationality."

In the hands of historians, critical theory proved a useful tool because it allowed them to place newfound importance on popular culture by treating it as a complex, multisited industry that emerged in conjunction with industrial modernity. Thus a scholar like John Kasson (1978) could describe the amusement parks of Coney Island as "laboratories of the new mass culture" (p. 8). The great appeal of the parks, Kasson argued, derived from their proprietors' skills at "sustaining the illusion of anarchic freedom and heedless release beneath the underlying reality of control" (p. 82). No matter how terrifying the "Loop the Loop" may have felt at full hilt, thrill seekers could rest assured that modern engineering kept it all very safe. Taking a similar approach, Jackson Lears (1994) could frame the rise of Madison Avenue as less the triumph of materialism than the height of managerialism. "Consumer culture there was . . .," Lears acknowledged, "but it was less a riot of hedonism than a new way of ordering the existing balance of tensions between control and release" (pp. 10–11). Even scholars working in a less overtly theoretical vein, such as business historian Roland Marchand (1998), unmistakably framed media as a site of ideological production. Thus, for Marchand early public relations could be described as big business's carefully engineered response to popular unease about the scale and "soullessness" of corporate commerce.

What these works shared was a baseline recognition that mass culture is the product of complex bureaucratic processes and social relationships that intersect with the larger workings of consumer capitalism. Similarly, they recognized the asymmetrical nature of modern media culture. It made a difference, as Lears (1992, pp.

1422–1423) argued, “that some groups or classes had the capital to mass produce and mass market cultural forms, while other groups had to make the best of what they bought.” Moreover, by sticking close to concepts – rationalization, standardization, control, and commodification – rather than lapsing into a conspiratorial mindset, they were able to make compelling connections between culture and consciousness.

Scholars working in British cultural studies drank from the same theoretical waters and were concerned with many of the same issues. In their hands, however, these ideas oftentimes looked quite different. The “culture” in cultural studies has had a shape-shifting quality and its various iterations have had a tremendous impact on both media scholars and cultural historians. In cultural studies’ formational years, culture referenced two specific intellectual projects. The first – tackled in the early work of Raymond Williams, Richard Hoggart, and E. P. Thompson – was to pry the culture concept away from the guardians of Culture with a capital C by showing that ordinary forms of expression and ways of being – even in industrialized society – were just as worthy of the name. In short, the aim was to upend cultural hierarchy by replacing notions of culture as “the best and the brightest that has been thought” with an anthropological conception of culture as a “whole way of life” (Hall, 1980).

The second project built on the first, but shifted focus toward reconciling this new definition of culture with materialist conceptions of socioeconomic power. Marxist thought had long operated according to a base–superstructure model, placing only things economic on the left side of the hyphen and piling up everything else to the right of it. This meant that whatever economic base prevailed during a particular phase of history was thought to determine the cultural possibilities that could take shape. Williams and Thompson challenged this assumption early on by demonstrating that new economic orders were created *within* and *through* culture, not outside of it (Hall, 1980). As Thompson (1963, p. 9) famously put it: “The working class did not arise like the sun at an appointed time. It was present at its own making.” Instead of a preordained demographic category, then, class was reconceived of as a process that was always carried out through cultural practices that, in time, congealed into institutionalized forms of social inequality. Williams put it differently, but also stressed the embedded nature of class. Using a chemical metaphor, Williams (1961) likened the culture of a given place and time, or “structure of feeling” (p. 64), to a “solution” (p. 63) that seamlessly incorporated all of the various elements of life – economic, social, cultural – into a complex whole that intuitively made sense from within. “The art is there, as an activity, with the production, the trading, the politics the raising of families” (p. 61).

Yet despite its strides toward debunking the simple base–superstructure model, this new understanding of culture remained unsatisfactory for materialists (Thompson and Williams included) who still felt that matters economic weighed disproportionately on lived experience. Most problematic was that these new definitions had difficulty accounting for the inertia of class dynamics, or their remarkable powers to reproduce themselves. Much of the field’s intellectual energy from the mid-1960s to the late 1970s was devoted to working through this problem. For Williams (1977),

the solution lay in a cultural materialist understanding of history. From this vantage point, culture was “constitutive and constituting” (p. 100) in that it was baked into the material processes by which society made and remade itself. As Williams (1980) saw it, this was a dynamic process, but it was by no means a democratic one because entrenched interests generally – but importantly, not always – held sway over “our assignments of energy; our ordinary understanding of the nature of man and his world” (p. 38). Stuart Hall built on this cultural materialist approach by infusing it with notions of ideology and interpellation drawn from French structuralist thought. The result was a vision of culture as a broad plain of ideological struggle: a site where asymmetrical power was reproduced, contested, or sometimes simply overlooked as individuals actively made sense of social reality and their place within it (Hall, 1980).
